## GULF COAST WATER AUTHORITY RESERVOIRS A AND B VOLUMETRIC AND SEDIMENT SURVEY REPORT

## INTRODUCTION

Staff of the Surface Water Availability Section of the Texas Water Development Board (TWDB) conducted a volumetric and sediment survey of The Gulf Coast Water Authority's (GCWA) Reservoirs A and B on June 30, and July 1, 2004. The purpose of the survey was to determine the current storage capacity and volume of sediment in the reservoirs at maximum pool elevation 18.2 feet (local datum). Survey results are presented in both tabular and graphical form in Appendices A through G.

The vertical datum used during this survey is that used by GCWA for the staff gauge located on the A reservoir's discharge structure. TWDB staff did not establish the datum of this gauge; therefore, for the purposes of this report the datum will be considered a local datum. GCWA's Reservoirs A and B are off-channel reservoirs located in Gulf Coast, near the towns of La Marque and Texas City (see Figure 1), and filled with diversions from the Brazos River. The reservoirs are contained within two levees that were constructed from material taken from a ditch that follows the levees around the interior of the reservoirs. The outer levee is approximately 4.8 miles, with an inner levee of approximately 1.3 miles surrounding and separating Reservoir A from Reservoir B (see photo Figure 2). However, Reservoirs A and B are essentially one reservoir joined together by two regulated "equalizer" pipes located on the east side of the northeast corner of the inner levee that separates Reservoir A from Reservoir B as well as four unregulated pipes located through the inner levee. Construction of the reservoirs was completed in $1949{ }^{1}$.

Currently, the GCWA operates Reservoirs A and B under the authority granted to them in Certificate ${ }^{2}$ of Adjudication No. 12-5168. Permission was given to "maintain an existing 7,308 acre-foot capacity off-channel reservoir and to impound therein not to exceed 7,308 acre-feet of water." For more information about the uses, diversion locations, priorities and special conditions, please refer to the Certificate of Adjudication 12-5168, on record with the Texas Commission on Environmental Quality (TCEQ).

## SURVEY METHODS, EQUIPMENT, AND DATA PROCESSING

## Methods

A reservoir boundary, used in preparing a transect line file, was first developed using Geographic Information System (GIS) software ${ }^{3}$ and 1995 aerial photos (Figure 2).

Transects or range lines were drawn using commercially available hydrographic surveying software ${ }^{4}$. The survey crew arranged these transects in a grid pattern with 500 ft spacing and perpendicular to each other and then used these for navigation purposes on the reservoirs. Actual boat course is shown in Figure 3.

Figure 3. Location of data, collected in 500-foot grid pattern, in Gulf Coast Water Authority's Reservoirs A and B. The six openings in the inner levee were incorporated to connect the reservoirs in the TIN model and are not drawn in their actual location in this figure.

During the data collection phase of the survey, the crew navigated the boat along each transect line using a Global Positioning System (GPS) receiver integrated with the surveying software. Depth reading from a multi-frequency sub-bottom profiler and positional data from the GPS were recorded on an on-board computer for each transect
line. Survey team members periodically checked the depths and sediment thickness using a survey stadia rod. Figure 4 represents the modeled sediment location and three locations where the survey crew verified depth readings and made coarse sediment thickness measurements. Figure 5 overlays Figures 3 and 4 highlighting estimated sediment with collected data.

Figure 4. Estimated location and thickness of sediment found in Reservoirs A and B.

Figure 5. Figures 3 overlaid with Figure 4 illustrating data density with estimated sediment thickness.

After all the depth and positional data were collected, they were stored for later retrieval. The data were processed and imported into the GIS software for developing a
triangular irregular network ${ }^{5}$ (TIN) model of the lake bathymetry. Surface areas and volumes were calculated from the TIN for 0.1 ft increments.

## Equipment

The equipment used to perform the survey consisted of a 20 -foot aluminum, shallow-draft, flat bottom SeaArk craft (River-Runner) with cabin and equipped with a 100-horsepower Yamaha outboard motor. To collect data on board, we used a Specialty Devices, Inc. (SDI) multi-frequency ( $200 \mathrm{kHz}, 50 \mathrm{kHz}$, and 24 kHz ) sub-bottom profiler ${ }^{6}$, and a Trimble Navigation, Inc. AG132 GPS receiver with Omnistar ${ }^{7}$ differential GPS correction signal. On board the River-Runner boat, the survey crew calibrated the SDI sub-bottom profiler depth sounder using a DIGIBAR-Pro Profiling Sound Velocimeter from Odem Hydrographic Systems ${ }^{8}$.

## Data Processing

Each raw data file was processed through the DEPTHPIC program, which graphically displayed the acoustic record collected by the SDI sub-bottom profiler and allows the operator to change the weighting of each frequency to highlight different sediment characteristics ${ }^{6}$. The lake post- and pre-impoundment surfaces were then digitized and stored for further processing. The 200 kHz frequency was used to define the present post-impoundment surface, and the 50 kHz frequency was used to estimate the pre-impoundment surface (see Figure 6). The water surface elevation of the reservoirs for each day was then added to the post-processed data, converting depths into local datum elevations. After all changes had been made to the data files, they were then saved and combined into a separate $\mathrm{X}, \mathrm{Y}, \mathrm{Z}$ data file for each frequency.

Figure 6. The 50 kHz signal profile in Reservoir B shows the approximate preimpoundment boundary (yellow line) and ditches on each end of profile. The light gray and black-white speckled signal response was interpreted to be the sediment layer without corroboration with core samples. The lighter gray area is most probably a fine particle, low-density mud with high water content. See Figure 8 for location of profile.

The resulting data files were imported into ESRI's Arc/Info Workstation GIS 8.3 software ${ }^{3}$. This software was used to convert each data set into a MASS points file. The MASS points and the boundary file were then used to create a Digital Terrain Model (DTM) of the reservoirs pre- and post-impoundment surfaces using Arc/Info's TIN software module. The module generates a triangulated irregular network (TIN) from the data points and the boundary file using a method known as Delauney's criteria for triangulation ${ }^{5}$. Using this method, a triangle is formed between three non-uniformly spaced points, including all points along the boundary. If there is another point within the triangle, additional triangles are created until all points lie on the vertex of a triangle. All of the data points are used in this method. The generated network of threedimensional triangular planes represents the bottom surface. With this representation of the bottom, the software then calculates elevations along the triangular surface plane by determining the elevation along each leg of the triangle. The lake area and volume can be determined from the TIN created using this method of interpolation.

Volumes were calculated for the post-impoundment surface ( 200 kHz frequency) and the pre-impoundment surface ( 50 kHz frequency) (Figures 6 and 7) and then subtracted from each other to derive the estimated total post-impoundment sediment.

Figure 7. Color composite profile of 200 (red), 50 (green) and 24 kHz (blue) shown in Figure 6.

Figure 8. A 50 kHz signal profile running along the ditch. The location of this profile is shown in Figure 9.

Figure 9. The southeast corner of the reservoirs showing the locations of transects shown in Figures 6, 7, and 8.

## RESULTS and DISCUSSION

The results of the TWDB survey indicate that Reservoirs A and B have a combined surface area of 859 acres and contain a volume of 7,360 acre-feet of water at gauge elevation 18.2 feet. Survey team members estimated the volume of sediment in the reservoirs to be 750 acre-feet for an average annual loss of approximately 13 acre-feet per year for the 56 -year period between 1949 and 2004. For this report the sediment data was not independently verified by any other means, such as core sampling. However, survey team members did probe the sediment with a stadia rod from which depth of sediment can be roughly inferred. The position of the sediment correlated well with a GCWA 1997 investigative survey however, sediment thickness varied significantly within the ditch around the reservoirs when compared to GCWA investigative survey. Figure 4 shows approximate sediment location and thickness. A large area of Reservoir B had little or no sediment, most of it being found in the southern end of the reservoir and in the ditch.
