Statewide Water Conservation

Quantification Project

Texas Water Development Board Research Project

Prepared by Averitt & Associates, Inc.

August 2017

Acknowledgements

The authors of this report wish to sincerely thank the many people that assisted with the compilation of this report.

Many busy water utility staff took time to learn about the project and spent time gathering the data that was fundamental to the development of this report. We recognize and acknowledge their efforts.

The good folks at the wholesale water providers helped us in many ways including outreach to their retail customers, data collection, and by providing invaluable background information. Efforts were coordinated with wholesalers who have shown a serious commitment to municipal water conservation.

The professional staff at the Texas Water Development Board were assisting every step of the way. Guidance and technical support were provided throughout the entire project. The assistance provided was invaluable.

The regional planning groups assisted by giving the authors an audience to explain the project across the state, and by helping with outreach.

The authors learned a tremendous amount during the course of preparing this report. Many organizations were consulted that have a vested interest in water conservation in Texas. Some of these groups are the Alliance for Water Efficiency, the Texas Water Foundation, the Water Conservation Advisory Council, the Lone Star Chapter of the Sierra Club, and many others. The combined experience and knowledge of these groups led to a deeper understanding of the nature of conservation activities in our state.

The report was greatly enhanced thanks to the input from all of those who took an interest.

Statewide Water Conservation Quantification Project
State Report • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Project Approach

The project team completed these steps to address each task:

- Engaged more than 230 water utilities to participate
- Interviewed and collected data from 170 utilities that ultimately participated
- Measured and quantified more than 547 individual conservation activities
- Produced 170 individual reports that included quantified activity savings, water loss reduction savings, individual conservation goal assessment, state water plan goal assessment, and suggested activities that are attainable and meet state water plan goals in the future

- Produced 15 regional reports that detail each region's progress in meeting the recommended regional water plan conservation goals
- Produced one state report summarizing the results of the project

1.2 Key Findings

- Participating utilities make up more than 17,000,000 in population by 2020, which is more than 58 percent of the state's total projected 2020 population.
- Participating utilities make up 77.5 percent of the state's recommended 2020 municipal conservation goal (supply volume).
- With the current conservation activities of 170 participating water utilities in place—and without further enhancement—Texas is projected to exceed its recommended 2020 water conservation supply volume by 95,947 acre-feet per year.
- Nine out of 15 regional water planning areas surveyed are also projected to exceed their 2020 supply volumes.
- These conservation savings estimates will fall short of the state's 2030 supply volume by 7,670 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of 170 participating water utilities in place—and without further enhancement—these 170 utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 136,981 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2040 supply volume by 44,409 acre-feet per year, but will fall short of their 2050 volume by 6,409 acre-feet per year.
- Considering only participating utilities' supply volumes, 14 out of 15 regional water planning areas surveyed are projected to exceed their 2020 supply volumes.
- Of those utilities surveyed, the state averages 3.2 measurable conservation activities performed per utility
- Utilities with greater than 100,000 people average 5.9 measurable conservation activities, while utilities with less than 50,000 average 2.2 measurable conservation activities
- One activity—an ordinance that permanently limits outdoor watering to twice per week or less—is projected to save 112,223 acre-feet per year in 2020 by the 46 utilities that have adopted it.

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

1.3 Observations

This report acknowledges that there are many facets involved in the state water planning process that are designed to ensure that Texans have enough water in the future, namely that demands and water management strategies are based on dry-year or drought of record conditions. It is also clear that for most water management strategies in the State Water Plan, the current planning methods are the most logical and effective way to address needs (potential shortages) that will arise in the future.

However, the way water management strategy (WMS) supply volumes for municipal conservation are developed do not facilitate an easy assessment by the utilities expected to meet these future supply volumes.

For instance, WMS supply volumes in regional water plans are derived from making incremental reductions to a municipal water user group's (WUG) starting point regional water planning gallons per capita per day (GPCD)[2] value each year until a certain GPCD value is reached.

But a city or utility looking at its regional water plan cannot easily assess what the starting point GPCD—or the formula used produce that GPCD value—was to derive its WMS supply volume. If utilities are recommended to achieve these volumes, this makes it difficult for a utility to realistically track its progress versus the plan.

Meanwhile, utilities are tracking total GPCD progress on their own, but are using a different GPCD formula[3] when they submit 5- and 10-year goals as required in the TWDB's water conservation plan annual reports and five-year water conservation plans.

From engaging with utilities with limited staff and resources, it was also evident that comparing whether an acre-feet per year supply volume is being met is difficult when the utility reports and operates using gallons.

Lastly and perhaps most crucially, the decision makers at utilities (i.e. reporting entities) that are responsible for affecting conservation policy and implementing activities aimed at meeting WMS supply volumes are sometimes different than those that would be able to affect conservation for WUGs (or political subdivisions). For example, some municipal utility districts operate within city boundaries and, indeed, serve cities, but are not required to carry out any conservation activities that a city council may want to pursue. Yet, supply volumes in the plans are still apportioned to such cities or, in the opposite case, are apportioned to municipal utility districts that cannot actually decide whether to pursue conservation efforts to meet such volumes.

---

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[3] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

1.4 Recommendations

The water savings projections from this project are promising, but only represent a current snapshot of how the state is performing in an area that will be crucial for future municipal water needs. A practical method to annually estimate and measure the implementation of conservation activities statewide would be the best solution.

The state should potentially develop a process to standardize and improve bottom-up (as described in Section 5) conservation savings estimates. This approach should provide consistent regional and statewide conservation estimates, and could provide a common data collection and reporting system that state, regional, and local agencies could access and, over time, create a robust database of conservation data (BBC Research and Consulting, 2012). By establishing such a system to annually estimate bottom-up savings to compare with savings results from the top-down approach currently being employed by the state, an understanding of true conservation savings would emerge and should help water planners to gauge conservation on a yearly basis, rather than every five years with much greater uncertainty.

It is possible that such an improved system would allow state water planners to synchronize yearly goals with metrics that match utilities' make up, goal assessment methods, and decision-making structure so that implementation and meeting goals could become seamless.

This report also makes the following recommendations, which are expanded upon in Section 9.

1. Regional Water Planning Groups (RWPGs) can play a vital role to educate, but should not be expected to drive conservation efforts.

2. Wholesale water providers (WWPs) should function as key stakeholders and drivers of monitoring, measuring, and reporting conservation activity to their customer cities and utilities.

3. Consider using a stakeholder group to form a consensus on savings estimates for activities being implemented throughout Texas.

4. Utilities should consider the suggested activities listed in each of the individual reports issued as part of this project.

2 Introduction and Background

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

This percentage, which amounts to 811,224 acre-feet per year by 2070[4], is significant not only because of the sheer volume of water it represents, but also because of the dramatic population influx that is expected in the urban and suburban corridors over the next 50 years. The state water plan estimates that the six most populous regions—Regions C, G, H, K, L, and M—will increase in population by 79.5 percent from 2020 to 2070. In Region C, 29 percent of 2020 water supplies are slated to come from municipal conservation, while in Region L, 13 percent is expected from this strategy (Texas Water Development Board, 2017). That makes conservation, and municipal conservation in particular, an indispensable piece of the water supply puzzle.

Texas prides itself on being a great place to live and work. However, a fundamental key to the success of the state's economic future is the availability of affordable water supplies.

In short, Texas must meet these expected municipal conservation supply volumes in the future or it will eventually have to make them up with much costlier options, such as new reservoirs or securing additional water rights.

So, it is known that municipal conservation is a vital component of the planning process, yet it is one of the most difficult to measure uniformly and assess on a scale larger than one or several utilities. In 2015, the Texas Legislature appropriated funds to the TWDB to fund a research project to address this problem. Among other tasks, the project was charged with measuring and quantifying the municipal water conservation activities being implemented by utilities throughout the state to determine whether recommended supply volumes for municipal conservation are being met.

2.1 Project Objectives

Using legislative language as guidance, the TWDB developed specific tasks for the project. The following tasks were the core components to completing this state report, 15 regional reports (Region I utilities did not meet selection criteria), and 170 individual utility reports:

> **Task 1**: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 2**: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 3**: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.
>
> **Task 4**: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

[4] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for the whole state are 203,757 acre-feet per year for 2020, 332,799 acre-feet per year for 2030, 434,947 acre-feet per year for 2040, 562,148 acre-feet per year for 2050, and 685,621 acre-feet per year for 2060.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

3 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a WUG refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

3.1 Regional Planning Group Approach to Determining Supply Volumes

Each RWPG is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce GPCD consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD[5] and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached, after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not recommend further reductions in GPCD for WUGs once they reach 140 GPCD, while others apply only "advanced conservation" activities once WUGs meet 140 GPCD.

4 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the RWPGs, direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

---

[5] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

More than 230 utilities were invited to participate and 170 accepted and were part of the results for this project. For a full list of all utilities that were invited and participated by region, see Appendix B.

5 Project Approach

The following question was used as the basis for developing an approach to complete project:

> *How can conservation activity be measured accurately on a large scale to ensure Texas is meeting the marks set out in its State Water Plan?*

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to simply compare GPCD consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology and Quantifiable Savings

6.1 Methodology

In order to complete a uniform quantification process, as much relevant data as possible was collected from participating utilities. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes. The results of this process are detailed in Section 7.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[6] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[7] for that year.[8] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before

[6] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[7] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).
[8] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[9] for water loss GPCD[10] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[10] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

6.3 Calculating Activity Savings

This study uses four methods meant to estimate conservation savings as accurately as possible over time. The useful life, decay rate, and partial adoption methods were used in conjunction with one another when the attributes of a particular activity (e.g. a device) required it based on supporting savings estimates. The utility demand-based method was applied on its own without interaction from the other three methods employed.

The following explanations separate the methods to illustrate the concepts involved when calculating savings estimates. All annual savings estimates and variables used for each activity are included in each individual utility report completed for this project.

<u>Utility Demand-based Method</u>

The first method estimates savings based on utility demand. Certain activities are estimated to result in a percentage reduction in use for certain targeted customer classes (multi-family customers, e.g.), targeted types of use (indoor use, e.g.), or for the utility's total use.

For this project, if a utility had future demand estimates available through the interview process or its five-year water conservation plan, those projected water supply requirements were used to apply the percentage of reduction the activity is anticipated to accomplish in future years. The State Water Plan's (2017) decadal demand volumes were used to establish annual demand estimates for those utilities that had not estimated demand decades into the future.

Note that savings estimates derived from State Water Plan demand figures may be higher than some derived from utility-supplied demand figures, because, "Texas' state water plans are based on future conditions that would exist in the event of a recurrence of the worst recorded drought in Texas' history—known as the 'drought of record'— a time when, generally, water supplies are lowest and water demands are highest" (Texas Water Development Board, 2017).

For an activity such as an ordinance permanently limiting outdoor watering to two times per week (or less), it is assumed that as demand increases year over year, the savings estimate increases at the same rate. The reasoning is that estimated annual savings are expressed as percentage of the utility's total demand. It follows that while the ordinance remains in place, new customers must abide by the same stipulations and expected demand will continue to be reduced by the same percentage each year (Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015). The savings estimated using this assumption matched closely with the specific estimates made by cities that have measured the effect of such an ordinance in their service areas, such as the cities of Allen, Austin, et al.

Table 6-1 is an example that shows how savings estimates would be derived using this method when savings are estimated to result in eight percent savings of a utility's total demand. Accuracy for any of these methods would be improved if estimates were compared to actual usage throughout an entire analysis year.

Table 6-1. Example of Estimated Savings from Permanent Twice-per-week Outdoor Watering Restriction in Region C.

Year	Population	Demand (MG)	Percent Savings Due to Activity	Estimated Savings Annual Savings (MG)
2012	101,695	6,471	8%	518
2013	102,622	6,657	8%	533
2014	103,550	6,842	8%	547
2015	104,477	7,028	8%	562
2016	105,405	7,214	8%	577
2017	109,780	7,399	8%	592
2018	114,155	7,585	8%	607
2019	118,529	7,771	8%	622
2020	122,904	7,956	8%	636
2021	127,279	8,142	8%	651
2022	130,373	8,327	8%	666
2023	133,467	8,513	8%	681
2024	136,560	8,699	8%	696
2025	139,654	8,884	8%	711
2026	142,748	9,070	8%	726
2027	145,842	9,256	8%	740
2028	148,936	9,441	8%	755
2029	152,029	9,627	8%	770
2030	155,123	9,813	8%	785

Useful Life Method

This method applies 100 percent of an annual savings estimate for the entire useful life of a device or fixture replacement. A device can be defined as a physical object that is installed or otherwise deployed by the utility or utility customer that reduces water use, such as an irrigation controller or rain barrel. A fixture can be defined as a part that is attached to a system of pipes that carries water to a customer, such as a toilet, showerhead, or kitchen faucet. Estimating savings by this method assumes that the device or fixture lasts for the duration of its useful life estimate.

Table 6-2 shows how savings would be estimated for a suburban utility in Region K that has rebated, sold, or otherwise distributed 50-gallon rain barrels within its service area for the years 2012 – 2015. In this example, the utility has deployed 680 barrels in 2012, 548 in 2013, 812 in 2014, and 290 in 2015.

GDS Associates (2002) estimates that a 75-gallon barrel for a suburban utility in this region yields 4.6 gallons per day per barrel, or 1,679 gallons per year per barrel. Because the utility in the example deployed 50-gallon barrels in the service area rather than 75-gallon barrels, a ratio can be used to determine approximate savings for the smaller capacity barrel:

$$\frac{75}{1{,}679} = \frac{50}{X}$$

The savings estimate per 50-gallon barrel per year is thus 1,119 gallons per year. With a useful life of 10 years, the savings remain constant each year for 10 years. As more barrels are introduced into the service area in subsequent years, the savings aggregate while the barrels are still assumed to be useful. If the program is discontinued, savings from this activity will eventually dissipate after the last group of barrels has been in the service area for 10 years.

Table 6-2. Example of Estimated Savings from 50-gallon Rain Barrels in Region K.

	2012	**2013**	**2014**	**2015**	**TOTAL (gallons)**	**TOTAL (MG)**
2012	761,600	0	0	0	761,600	0.8
2013	761,600	613,760	0	0	1,375,360	1.4
2014	761,600	613,760	909,440	0	2,284,800	2.3
2015	761,600	613,760	909,440	324,800	2,609,600	2.6
2016	761,600	613,760	909,440	324,800	2,609,600	2.6

Annual Decay Rate Method

Table 6-3 demonstrates the next method which estimates full annual savings for the first year of implementation of an activity and then applies an annual decay rate for the following years the activity is useful.

An annual decay rate means that initial estimated savings decrease by a percentage after a year's time due to gradual loss of effectiveness that can occur for a variety of reasons. An outdoor irrigation (or lawn) audit for single-family (SF) customers is one common activity to which a decay rate is attributed. During an on-site audit, utility staff (or a third-party vendor) assesses the customer's current irrigation system and practices, and may adjust irrigation scheduling and timers, provide efficiency tips, perform a catch-can test or a number of other water-reducing actions. Over time, however, some participants may lose interest in continuing behavior learned from the visit or a device, such as an irrigation timer, may cease to function properly and is never replaced by the customer. While not perfect, applying annual decay rates helps to account for these decreases in savings that have been documented in field studies.

According A&N Technical Services (2005), some audits include an indoor component as well as an outdoor component. In addition, different savings result from lawn audits performed for customers with an irrigation timer than for those without one. For this estimate, unless specific savings or customer details were presented, it is assumed that an outdoor-only audit achieves savings of approximately 8,000 gallons per year per audit with an annual decay rate of 20 percent.[11] As with many other activities with decay rates, the study's authors acknowledge "the persistence of water savings from residential [audits] remains a difficult quantity to predict."

In this example, the utility has conducted 398 audits in 2012, 540 in 2013, 365 in 2014, and 495 in 2015. Applying the annual decay rate results in 80 percent of total savings the following year, 60 percent savings the third year, 40 percent savings the fourth year, and 20 percent savings the fifth year. By the sixth year, savings have approached zero.

Similar to the useful life method, as more audits (or units of another activity with a decay rate) are performed in the service area in subsequent years, the savings from previous audits begin to aggregate when there is overlap over time.

Table 6-3. Example of Estimated Savings from Outdoor Audits (SF).

	2012	2013	2014	2015	TOTAL (gallons)	TOTAL (MG)
2012	3,184,000	0	0	0	3,184,000	3.2
2013	2,547,200	4,320,000	0	0	6,867,200	6.9
2014	1,910,400	3,456,000	2,920,000	0	8,286,400	8.3
2015	1,273,600	2,592,000	2,336,000	3,960,000	10,161,600	10.2
2016	636,800	1,728,000	1,752,000	3,168,000	7,284,800	7.3
2017	0	864,000	1,168,000	2,376,000	4,408,000	4.4
2018	0	0	584,000	1,584,000	2,168,000	2.2
2019	0	0	0	792,000	792,000	0.8
2020	0	0	0	0	0	0

[11] This assumes that 65 percent of savings from a full indoor and outdoor audit comes from the outdoor component (Whitcomb, 2000) (8,000 gallons per year), or if the audit was strictly an outdoor irrigation audit, that 70 percent of savings came from customers with an irrigation timer while 30 percent of savings came from those without one (7,953 gallons per year). The 20 percent decay rate was an assumption selected from a range of possible decay rates for measures within the activity, which incorporated indoor and outdoor elements and sourced several field studies.

Savings Based on Partial Adoption of Activity Method

The fourth method uses the principles of the useful life and decay rate methods, but also factors in an assumption that market penetration—or the adoption of a given activity by customers in the service area—is less than 100 percent.

For example, if a utility reports that 100 take-home water-saving device kits were distributed in a service area in a given year, but a supporting study indicates that the general adoption (or utilization in this case) rate of the kits is 15 percent, then savings would only be estimated for 15 kits out of the 100 distributed. If applicable, normal useful life and decay rates would also apply over time, and savings would aggregate as the useful life of the units overlap in consecutive years.

6.3.1 General formulas used for activity savings

Because not every estimated savings result from field studies will agree with one another—indeed, many studies use an average of multiple results—the following is a presentation of the general formulas used for the activities quantified during this project. Some savings estimates are affected by regional, utility, vendor, weather, time-of-year, or other differences. In addition, savings estimates may be refined or adjusted as new technologies become available or a particular activity is further analyzed.

By using the methods and general formulas in Section 6, utilities interested in quantifying similar activities can substitute annual savings, percentage savings, useful life, and decay rate estimates as they see fit. To see the actual savings estimates and variables used to quantify each utility, refer to Section 3 of any individual report.

Utility Demand-related Activities

Water Savings (MG) = Annual Utility Demand x Percentage Reduction Expected for Activity

Water Savings (MG) = Annual Utility Demand for Type of Use x Percentage Reduction Expected for Activity

Water Savings (MG) = Annual Utility Demand for Customer Class x Percentage Reduction Expected for Activity

Useful Life and Decay Rate Activities

First Year: Water Savings (MG) = Activity Annual Savings in Gallons x Number of Units Per Year ÷ 1,000,000

Subsequent Years for Useful Life: Water Savings (MG) = Activity Annual Savings in Gallons x Number of Units Per Year x Annual Decay Rate* ÷ 1,000,000

*if applicable

Partial Adoption Activities

First Year: Water Savings (MG) = Activity Annual Savings in Gallons x Number of Units Per Year x Adoption Rate ÷ 1,000,000

Subsequent Years for Useful Life: Water Savings (MG) = Activity Annual Savings in Gallons x Number of Units Per Year x Adoption Rate x Annual Decay Rate* ÷ 1,000,000

*If applicable

6.3.2 Specific activity savings

Utility Demand-related Activities

1. **Advanced Metering Infrastructure System with Customer Portal**

Percent Reduction in End Use Expected: 1.34 percent of total demand

Based on an average from five studies performed for several sizes of utilities in different parts of the United States, the potential savings estimate assumes that 20 percent of customers actively using the customer portal will save 10 percent of household use[12] (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015).

Residential customers' use is assumed to make up approximately 67 percent of all retail customers' use based on utility profile information submitted to the TWDB, because this was the most common percentage of residential use among participating utilities in the project. Actual customer class demand percentages will vary by utility and were taken into account for utilities that are actually employing this activity. This activity was suggested for all other participating utilities. Meter data management (MDM) and customer portal brands were also given specific savings estimates when a supporting study was available.

2. **Conservation Pricing**

Percent Reduction in End Use Expected: 2.5 percent

To increase confidence level for an activity that has high variability in results, this percentage is conservatively estimated at 50 percent of the benchmark savings value of 5 percent estimated by the U.S. Environmental Protection Agency (U.S. EPA, 1998).

Confidence: Medium

[12] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

3. Twice-a-week Outdoor Watering Restriction Ordinance

Percent Reduction in End Use Expected: Ranges between 2.74 percent and 13.47 percent of total demand based on percentage of outdoor water use by the utility's single-family customers

Using utility-reported annual savings from total municipal use, a Texas Living Waters Project study (Sierra Club-Lone Star Chapter and the National Wildlife Federation, 2015) established a link between implementing an ordinance permanently limiting year-round outdoor watering to two times per week (or less) and the percentage of outdoor water use by single-family residential customers. Thirty-eight percent of outdoor use was found to correlate to water savings of eight percent, while 20 percent was found to correlate to nearly four percent. By further relying upon a TWDB study (Hermitte and Mace, 2012) that determined the percentage of outdoor residential water use in Texas for many utilities throughout the state's regional water planning areas, this project developed a range of potential savings. Table 6-4 details ranges used for individual utilities along the scale. Table 6-5 shows averages established to assign savings to a region if a specific utility's outdoor use was unknown.

Confidence: Medium-low

Table 6-4. Potential Percentage Reduction in Total Municipal Use from Permanent Twice-per-week Outdoor Watering Restrictions.

Outdoor Use Percentage of Total Use	Potential Percent Reduction in Total Use with Ordinance	Outdoor Use Percentage of Total Use	Potential Percent Reduction in Total Use with Ordinance
64	13.47	40	8.42
63	13.26	39	8.21
62	13.05	38	8.00
61	12.84	37	7.79
60	12.63	36	7.58

Region J	7.79
Region K	6.53
Region L	6.11
Region M	5.05
Region N	4.84
Region O	8.42
Region P	5.05

4. Water Rate Increases

Percent Reduction in End Use Expected: Based on price elasticities related to demand of approximately – 0.20, which translates into a reduction of two percent in water use for a 10 percent increase in price (U.S. EPA, 1998; TWDB, 2013; Whitcomb, 1999).

See Section 6.3.3 for caveats to this activity's savings estimates.

Confidence: Medium-low

Useful Life, Decay Rate, and Partial Adoption Activities

5. Efficient Urinal Installation (1/2 Gallon Per Flush) (ICI)

Annual Savings Estimate: 6,200 gallons per year per fixture or 16.9 gallons per day

Project savings estimate assumes an average of 22.5 flushes per day when replacing high-flow valve urinals. Source study assumes 260 working days per year on average for an Institutional-Commercial-Industrial (ICI) customer using the fixture (A&N Technical Services, 2005).[13]

[13] From the study's authors: "Much of the savings and cost information in this document has been published previously in other sources. Though we are grateful to build on this previous work, the errors that remain are our own." As such, this study serves as a summary of many studies relied upon by the California Urban Water Conservation Council over several years as more activities were analyzed.

Useful life for this fixture is generally 15 years, but savings are assumed to persist.[14]

Confidence: Low due to variability of flushes and working days by type of ICI customer

6. **Turf Replacement with Zero Irrigation Landscape**

Annual Savings Estimate: Gallons per year per rebate determined by establishing a baseline landscape water requirement for the customer base (LWR_1) and subtracting a landscape water requirement for the landscape design introduced (LWR_2)
Useful Life Estimate: 10 years

LWR_1 can be determined using the EPA WaterSense Formula (U.S. EPA, 2017):

$$LWR_H = RTM\ [(ET_o \times K_L) - R_a] \times A \times C_u$$

Where:

LWR_H = Landscape water requirement for the hydrozone (gallons/year)
RTM = Run time multiplier, equal to 1/low quarter distribution uniformity
ET_o = Local reference evapotranspiration (inches/year)
K_L = Landscape coefficient for the type of plant in that hydrozone (turf grass – low water requirement assumed for this activity)
R_a = Allowable rainfall, designated by WaterSense as 25 percent of average peak monthly rainfall
A = Area of the hydrozone (square feet)
C_u = Conversion factor (0.6233 for results in gallons)

LWR_2 for this activity is assumed to be zero. Certain landscapes, such as artificial turf, patios, and permeable hardscapes, require no irrigation. Thus, annual savings for this activity will be equal to LWR_1.

Confidence: Medium

7. **High-Efficiency Toilet Replacement Program (SF)**

Annual Savings Estimate: 10,390 gallons per year per fixture or 28.46 gallons per day

The high-efficiency toilet savings estimate for this project results from increasing the annual savings from the replacement of a 3.5 gallons-per-flush (gpf) toilet by an ultra low-flush (ULF) 1.6 gpf model by 23 percent.

The 23 percent takes into account the 1.19 gpf standard deviation that can result each time a 3.5

[14] Plumbing code and efficiency standards effectively make the savings permanent, as equally efficient models will replace these urinals by useful life's end.

gpf toilet is flushed[15] (AWWA Research Foundation, 1999). The volume difference between the 1.6 gpf and 1.28 gpf models is a precise 20 percent, but when adjusted standard deviation of toilet flush volumes is introduced for these models, the difference can be between 20 and 26 percent, or an average of 23 percent. See the ULF toilet replacement activity in this section for details on how estimated savings for the 1.6 gpf model was calculated.

Regarding decay rate or persistence as toilets are used, "[a]t least one field study tested for, and could not detect, any downward trend in the level of water savings amongst early participants in toilet programs..." (A&N Technical Services, 2005). Useful life for this fixture is generally 20 years, but savings are assumed to persist.[16]

Confidence: High

8. High-Efficiency Toilet Replacement Program (MF)

Annual Savings Estimate: 15,756 gallons per year per fixture or 43.17 gallons per day

The high-efficiency toilet savings estimate for multi-family (MF) customers also results from increasing the annual savings from the replacement of a 3.5 gallons-per-flush (gpf) toilet by an ultra low-flush (ULF) 1.6 gpf model by 23 percent. See the ULF toilet replacement (MF) activity in this section for details on how estimated savings for the 1.6 gpf model was calculated. Useful life for this fixture is generally 20 years, but savings are assumed to persist.[17]

Confidence: High

9. High-Efficiency Toilet Replacement Program (ICI)

Annual Savings Estimate: 13,000 gallons per year per fixture or 35.6 gallons per day

The high-efficiency toilet savings estimate for ICI customers results from increasing the annual savings from the replacement of a 3.5 gallons-per-flush (gpf) toilet by an ultra low-flush (ULF) 1.6 gpf model by 23 percent. See the ULF toilet replacement (ICI) activity in this section for details on how estimated savings for the 1.6 gpf model was calculated.

Confidence: High

---

[15] From the end use study: "Results from this research about the variability of toilet flush volumes indicate that toilets do not flush in neat little intervals like 1.6, 3.5, or 5.0 gpf. A toilet rated to flush at 3.5 gpf or 1.6 gpf will seldom use precisely that amount of water for a single flush, even when the toilet is new."
[16] See Footnote 14.
[17] See Footnote 14.

10. High-Efficiency Clothes Washer (SF)

Annual Savings Estimate: 7,030 gallons per year per washer or 19.2 gallons per day

Useful life for this device is generally 11 years (THELMA, 1997), but savings are assumed to persist if useful life ends in 2014 or after.[18] Estimated savings are an average of studies that yielded approximately 5,060 and 9,000 gallons per year per washer (A&N Technical Services, 2005).

Confidence: Medium

11. Kitchen Pre-Rinse Spray Valve Replacement (ICI)

Annual Savings Estimate: 28,280 gallons per year per fixture or 77.48 gallons per day

Useful life for this device is generally 10 years, but savings are assumed to persist if useful life ends in 2013 or after.[19] Estimated savings are an average of studies that yielded approximately 6,560 and 50,000 gallons per year per valve (SBW Consulting, 2007; California Urban Water Conservation Council, 2004).

Confidence: Low due to differences in ICI customer type that may use the valves more heavily

12. Low-Flow Showerhead Replacement (SF)

Annual Savings Estimate: 2,050 gallons per year per fixture or 5.6 gallons per day

Useful life for this fixture is generally five years, but savings are assumed to persist.[20] Estimated savings are an average of 5.5 gallons per day and 5.8 gallons per day with slight downtick due to statistical savings margin (A&N Technical Services, 2005).

Confidence: Medium-high

13. Low-Flow Showerhead Replacement (MF)

Annual Savings Estimate: 1,898 gallons per year per fixture or 5.2 gallons per day (A&N Technical Services, 2005)

Useful life for this fixture is generally five years, but savings are assumed to persist.[21]

Confidence: Medium-high

---

[18] See Footnote 14.
[19] See Footnote 14.
[20] See Footnote 14.
[21] See Footnote 14.

14. Rain Barrels

Annual Savings Estimate: Ranges by barrel capacity and by region

Using ratios based on savings for a 75-gallon barrel, Table 6-6 provides estimates by region to account for different size barrels that may be deployed in service areas. Useful life was conservatively estimated at 10 years, rather than 15 indicated in the source study (GDS Associates, 2002).

Confidence: Low due to rainfall variability

Table 6-2. Estimated Annual Savings per Gallon of Capacity for Rain Barrels by Planning Region.

Region	Savings per Gallon of Capacity
Region A	12.1
Region B	16.5
Region C	20.9
Region D	25.3
Region E	6.3
Region F	11.2
Region G	18.5
Region H	26.8
Region I	22.4
Region J	12.6
Region K	22.4
Region L	17
Region M	13.1
Region N	16
Region O	10.7
Region P	23.9

15. Outdoor Landscape Evaluations (SF)

Annual Savings Estimate: 8,000 gallons per year per audit
Annual Decay Rate: 20 percent

Some audits include an indoor component as well as an outdoor component. In addition, different savings result from lawn audits performed for customers with an irrigation timer than for those without one. For the estimate, unless specific savings or customer details were presented, it was assumed that an outdoor-only audit achieves savings of approximately 8,000 gallons per year per audit with an annual decay rate of 20 percent. This assumes that 65 percent of savings from a full indoor and outdoor audit comes from the outdoor component (Whitcomb, 2000)(8,000 gallons per year), or if the audit was strictly an outdoor irrigation audit, that 70 percent of savings came from customers with an irrigation timer while 30 percent of savings came from those without one (7,953 gallons per year).

The 20 percent decay rate is an assumption based on a range of possible decay rates for measures within the activity, which incorporated indoor and outdoor elements and sourced several field studies. As with many other activities with decay rates, the study's authors acknowledge "the persistence of water savings from residential [audits] remains a difficult quantity to predict" (A&N Technical Services, 2005).

16. Ultra Low Flush Toilet Replacement Program (SF)

Annual Savings Estimate: 8,440 gallons per year per fixture or 23.1 gallons per day per toilet (A&N Technical Services, 2005)

Savings per toilet per day estimated uses the formula:

Savings for Single Family Customer = 6.693 x Persons Per Dwelling – 0.529 x (Persons Per Dwelling)^2 + 7.826

Because multiple, in-depth studies for ULF toilet savings have long been available, ULF annual savings per toilet were used to develop savings estimate for high-efficiency toilets (1.28 gpf) for this project.

The project assumed three people per dwelling for this activity, and that an ULF toilet will be replaced by a high-efficiency model (1.28 gpf) due to current plumbing and efficiency code requirements once useful life of 20 years elapses.

Confidence: High. These estimates are based on rigorous field studies.

17. Ultra Low Flush Toilet Replacement Program (MF)

Annual Savings Estimate: 12,810 gallons per year per fixture or 35.09 gallons per day per toilet (A&N Technical Services, 2005)

Savings per toilet per day estimated uses the formula:

Savings for Multi-family Customer = 19.138 x Persons Per Unit – 0.942 x (Persons Per Unit)^2 + 2.181

Because multiple, in-depth studies for ULF toilet savings have long been available, ULF annual savings per toilet were used to develop savings estimate for high-efficiency toilets (1.28 gpf) for this project.

The project assumes 1.9 people per unit for this activity, and that a high-efficiency model (1.28 gpf) will replace an ULF toilet due to current plumbing and efficiency code requirements once useful life of 20 years elapses.

Confidence: High. These estimates are based on rigorous field studies.

18. Ultra Low Flush Toilet Replacement Program (ICI)

Annual Savings Estimate: 10,580 gallons per year per fixture or 29 gallons per day per toilet (A&N Technical Services, 2005)

The project assumes that ICI customers adopting this activity fall within the multiple use market segment that yields estimated savings of 29 gallons per day per ULF toilet installed. While the confidence interval for this assumption is lower than some other market segments, this estimate accounts for more variability among potential ICI customers.

Because multiple, reliable studies for ULF toilet savings have long been available, ULF annual savings per toilet were used to develop savings estimate for high-efficiency toilets (1.28 gpf) for this project.

Confidence: Medium due to multiple use market segment assumption.

Vendor-specific Activities

19. Save Water Co. Commercial, Multi-family and Hotel Programs

Calculated based on specific reported savings by vendor. See individual reports.

20. WaterWise Take-home Kits

Annual Savings Estimate: 7,384 gallons per year per kit (Frontier Associates, 2015)

Based on utility feedback, the project assumes a conservative adoption rate of 15 percent of all kits distributed through independent school districts, as well as a modest five-year useful life for all items in the kit.

21. W.I.S.E. Guys Audits

Annual Savings Estimate: 8,000 gallons per year per audit (A&N Technical Services, 2005)
Annual Decay Rate: 20 percent

More specific savings estimates were not available directly from the vendor; however, the vendor does perform very similar measures as assessed for savings for in-house utility audits.

6.3.3 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). During the project, it was noted that several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings Quantified by the Utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

Accelerated Plumbing Code Savings (PCS)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.3.4 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.3.5 Limitations to data collection and the interview process

The projections in this report indicate the best information available as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3.6 Discrepancies with regional water plans

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan.

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes split along regional boundaries.

7 Where Does the State Stand in Meeting Its Goals?

The 2017 State Water Plan recommends that Texas should achieve 811,224 acre-feet per year of savings annually to meet the 2070 WMS supply volume for municipal water conservation[22] (Texas Water Development Board, 2017).

The results of this study indicate that the 170 participating utilities surveyed in the state will save an estimated 278,747 acre-feet per year in 2020 and 405,446 acre-feet per year in 2070.[23]

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. Savings estimates from rate increases and water loss reduction are the only activities that are exceptions to these conditions for the reasons covered in Section 6.

If these current activities are maintained, Texas is estimated to exceed the state's adjusted[24] 2020 WMS supply volume of 182,800 acre-feet per year by 95,947 acre-feet per year. The savings from these utilities are estimated to fall short of the 2030 supply volume by 7,670 acre-feet per year, and the 2070 volume of 760,249 acre-feet per year by 354,803 acre-feet per year.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire state's 2070 recommended supply volume for municipal water conservation. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[25] for water loss GPCD[26] and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

---

[22] In an effort to match the Interactive State Water Plan and the planning document itself, the study has maintained the 2070 supply volume at 811,224 acre-feet per year for the entire state. However, in Region M, 50,441 acre-feet per year in 2070 are to be supplied by non-traditional irrigation district-related conservation that is slated to come from existing surplus. This differs from all other regions in the state, which classify municipal water conservation as a demand reduction measure. Thus, Table 7-1 has a 2070 supply volume of 760,249 acre-feet per year, as well as decadal volumes that account for the Region M anomaly. The quantified savings from all regions are compared to these adjusted volumes.

[23] Estimated savings are 298,248 acre-feet per year for 2030, 329,382 acre-feet per year for 2040, 355,555 for 2050, and 380,523 acre-feet per year for 2060.

[24] See Footnote 3 above.

[25] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[26] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total State WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire state.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total State WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the state for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

Table 7-1. Quantified Activity Savings of Participating Utilities Compared to Statewide WMS Supply Volumes.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total State WMS Volume	Unaccounted for Conservation WMS Volume
2015	166,360	48,047	214,408	81,245	133,163

2063	305,799	82,170	387,969	676,549	(288,580)
2064	307,609	82,855	390,464	688,507	(298,043)
2065	309,420	83,540	392,960	700,464	(307,504)
2066	311,233	84,225	395,458	712,420	(316,962)
2067	313,044	84,910	397,954	724,378	(326,424)
2068	314,854	85,595	400,449	736,335	(335,885)
2069	316,665	86,280	402,945	748,292	(345,347)
2070	318,478	86,969	405,446	760,249	(354,803)

Table 7-2 shows how the state's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the 170 participating utilities. These utilities constitute approximately 58 percent of the state's population and account for 77.5 percent of this water management strategy.

In this comparison, the utilities' savings are estimated to exceed the 2040 supply volume by 44,409 acre-feet per year, but just fall short of the 2050 supply volume by 6,409 acre-feet per year. Full regional tables in the same format as Table 7-2, can be found in Appendix A. The following definitions pair with the column headers in Table 7-2.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[27] for water loss GPCD[28] and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plans for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the state water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

---

[27] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[28] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

Table 7-2. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-3 lists the number of utilities in the state estimated to be meeting or not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the state as a whole.

Table 7-3. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Tables 7-4 through 7-7 show how the state's participating utilities, categorized by different population strata, are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The four strata are utilities with fewer than 10,000, between 10,000 and 49,999, between 50,000 and 99,999, and over 100,000 people. These tables contain the sum of the supply volumes for the participating utilities that fit into these population strata.

Table 7-4. Participating Utilities' (Under 10,000) Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

7.1 Participating Utilities' Progress in Meeting Five-year Water Conservation Plan Goals

Another task of this project required an assessment of whether participating individual utilities were meeting their five-year water conservation plan goals.

These plans are required by the TWDB to contain 5- and 10-year goals for total GPCD and water loss GPCD. [29]

Each individual report completed for this project includes in-depth analysis on whether these goals are being attained.

Table 7-8 shows how many participating utilities by region were meeting their water conservation plan goals for the year 2016, as well as if 5- and 10-year marks are being achieved. For nearly all utilities, the five-year goal is set for 2019, and the 10-year goal is set for 2024, because their most recent five-year conservation plan was drafted in 2014. Occasionally, these goals are sooner or further out based on when the last plan was submitted.

Table 7-8. Individual Utility Goals Achievement by Region.

Region	Total Participating Utilities in Region	Quantified Savings Only Meeting GPCD Goals			Most Current (2015) Water Loss GPCD Meeting Water Loss GPCD Goals			Most Current Total GPCD Meeting Total GPCD Goals

[29] The plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

8 Activity Findings

As one might imagine, surveying utilities with service area populations as small as 1,000 people and as large as 2.25 million people yielded quite the diversity of conservation activities being implemented. Many utilities perform no conservation activities outside of reducing water loss, while others vigorously pursue more than 35 unique measures.

By presenting activities with the highest incidence among participating utilities and showing the savings they each yield statewide, water planners should be able to glean which ones are most effective.

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values within the graph show how much these activities are saving statewide. In each regional report completed for this project, these same 12 activity categories and their savings are broken down for participating water planning regions.

For specific formulas used to quantify these activities, refer to Section 6.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[30] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

[30] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators, toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet per year).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

8.1 Ordinances Permanently Limiting Outdoor Watering to Twice Per Week (or less)

Twice-per-week outdoor watering ordinances save the most water of any commonly performed activity. Project data show that since 2011, 46 of the 170 participating utilities statewide have adopted the measure with 31 of those utilities located in Region C. With only 45 utilities pursuing this activity, it is estimated that this activity will be saving 112,223 acre-feet of water annually by 2020. By comparison, water loss reduction, which is an activity undertaken by all 170 participating utilities in the study, is projected to yield 54,473 acre-feet annually in 2020.

This activity has the added benefits of growing in savings as utility demand grows, permanency, and no direct cost to the customer. In fact, when using less water outdoors, customers will save money over time.

9 Observations on BMPs

In 2013, the TWDB released its "Water Conservation Best Management Practices: Best Management Practices for Municipal Water Users Guide" (Texas Water Development Board, 2013). The report was an update from a study originally compiled in 2004 and identifies 26 BMPs for municipal water users to consider, seven of which were updated from the 2004 report. One of the sections of the report offers guidance on how to quantify savings from these BMPs.

- The BMPs are considered a useful reference for utilities motivated to conserve. They have been vetted and revised by stakeholder groups such as the Water Conservation Advisory Council.

- Awareness of the Texas Water Development Board's BMPs is high.

- Utility staff, consultants, and regional planners refer to BMPs throughout their reports.

- Current TWDB reporting requirements includes a census of BMPs employed and estimated savings.

- As a tool for guidance they generally take a “top-down” approach when estimating savings, i.e. comparing consumption after the implementation of the activity to the water usage before the implementation of the BMP.

- Of the 26 BMPs, 14 of them roughly correlated to the measurable activities identified in this report. Of those 14, seven were similar to the PCS activities in this report. They had to do with toilets, aerators, and showerheads. Outdoor audits and surveys were four more that aligned generally with activities in this report. Conservation pricing, rain barrels, and water waste ordinances could also be aligned with this report.

- A census of which BMPs are being employed by individual utilities is required in the annual conservation reports. However, it was noted that there was some confusion on how the census was to be filled out.

- Some of the BMPs are rather broad in scope and sometimes instructions do not cover all possible interpretations. For example, BMP 7.4 calls for replacement of old shower heads, aerators, and toilet flappers. So when asked, a utility staff can answer “yes” to the question of implementation of this BMP even if their effort is to give away aerators and rain gauges at a local annual festival. They could also count this activity in 6.1 Public Information.

- There were several instances in the regional reports where the report authors lamented about the difficulty of estimating savings for BMPs. Many regional reports called for more data and guidance. Several of the recommended methods of quantifying savings require significant time and record keeping. They may not be practical for the overwhelming number of WUGs.

- If a “bottom-up” approach to measuring and quantifying water conservation is adopted, the Water Conservation Advisory Council should assist in aligning BMPs with specific conservation activities. A “bottom-up” approach allows for more granular analysis of specific activities, and the BMPs and specific activities should eventually align.

To summarize, the TWDB’s BMPs are highly regarded, well thought through methods of conserving water. And yet, for the purpose of measuring results, they are not well suited. With the help of stakeholders and a better, easier way to analyze data, the process of measuring the results of implementing BMPs could improve. Stakeholder involvement would be important in the development of a “bottom-up” approach to enhance the quantification of savings.

10 Recommendations

The following recommendations are focused on answering the question:

How can the state continue to meet the conservation supply volumes outlined in the State Water Plan?

1. **The RWPGs can play a vital role to educate, but should not be expected to drive conservation efforts.**

While the RWPGs obviously play a vital role in planning and ensuring that Texas' future overall water needs are met, ensuring that conservation supply volumes are met is not a role they are particularly well suited for. The composition, frequency of official meetings, and other functions they assume make it difficult for these entities to really increase implementation of conservation measures.

However, simply communicating the existence of recommended conservation supply volumes to the WUGs in their group could still be valuable.

2. **Wholesale water providers (WWPs) should function as key stakeholders and drivers of monitoring, measuring, and reporting conservation activity to their customer cities and utilities.**

WWPs are uniquely positioned to encourage conservation and achieve actionable results. These entities set water purchase rates and form water delivery contracts—two instances that provide opportunities to introduce conservation incentives. They have a direct interest in conserving as their water systems are expected to shoulder the burden of rapidly increasing populations and water demand. WWPs can also carry out district or system-wide conservation initiatives that can be adopted by cities with lesser resources.

The TWDB's Water Conservation Advisory Council recently adopted BMP that outlines this purpose and forward-thinking WWPs, such as Dallas Water Utilities, Lower Colorado River Authority, North Texas Municipal Water District, Tarrant Regional Water District, Upper Trinity Regional Water District, and others are already advancing this concept.

Here are several ways mentioned that WWPs can assist their customers with conservation:

- WWP conduct yearly water conservation plan implementation surveys to monitor progress of individual customer plan implementation and to *quantify* water savings from implementation of customer programs where possible.
- Develop a tracking system to track technical assistance and outreach activities
- Development of model water conservation plans and drought contingency plans that could be adopted by WWP customers
- Assistance to customers developing their own water conservation plans and drought contingency plans.

- Researching and providing advice on how to implement specific conservation programs or measures (Texas Water Development Board, 2013a)

3. **Consider using a stakeholder group to form a consensus on savings estimates for activities being implemented throughout Texas**

For many activities surveyed during this project, there are numerous credible studies that have been performed to determine reliable savings estimates. There are also similar techniques used to quantify savings for many of them. However, it would be useful and lend credibility to any future projects similar to this one, if stakeholders specific to the Texas water community could agree upon the most reliable estimates for as many activities as possible being performed throughout the state. As it stands, much of this information is only available from many different sources. A stakeholder group could centralize the effort and serve as a repository for agreed-upon savings estimates.

Quantifying water conservation is a process with inherent variables across regions and from utility to utility, but it is possible using the wealth of resources already available in the field to develop Texas-specific estimates for most activities being implemented in the state. Having those estimates would allow the work performed for this project to be repeated with more confidence, buy-in from interested entities, and widely accepted results.

4. **Utilities should consider the suggested activities listed in each of the individual reports issued as part of this project.**

Up to four activities were chosen as potential suggested activities in individual reports. These activities are: AMI systems with customer engagement portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings

Suggested strategies were chosen with the purpose of saving enough water to cover any shortages that a WUG may be facing in meeting its municipal conservation goals as recommended in their regional plan. Suggestions were also made to utilities that are meeting their goals, but may want to do more. The following is a description of the recommended strategies and why they were chosen. Also included is a brief explanation of why some other strategies—while effective—were not recommended.

AMI System with Customer Engagement Portal

This activity was included because of the potential AMI offers statewide. Interviews conducted around the state revealed that many utilities, from the smallest to the largest are considering some level of implementation of AMI. Of the 170 participating utilities, 89 already have some form of automated system. It is popular because it is effective in helping utility staff and their customers to have a better understanding of water usage. It helps detect leaks and saves administrative expenses, and as technology continues to improve, the feasibility of AMI can perform more functions and provide more data.

AMI is the most expensive recommendation, but can be eligible for favorable financing from the TWDB. Favorable financing and administrative savings makes AMI an achievable activity.

In addition, customer portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data.

Twice-per-week (or less) Outdoor Watering Ordinances

A twice-per-week (or less) watering ordinance is the most effective activity in terms of saving water. The impact of these ordinances can easily be seen in Region C. Within Region C, of the 63 participating utilities, 31 have implemented a twice-per-week outdoor watering ordinance. With ordinances in place, participating utilities are estimated to exceed their collective supply volumes by 64,277 acre-feet per year in 2020. Without such ordinances, those utilities are estimated to exceed their volumes by only 6,717 acre-feet per year in 2020. The ordinances are having a major impact on saving water. It also shows that the concept of twice-per-week is gaining momentum, and that the activity is achievable and returns outstanding water savings.

This recommendation has best results where there is a proliferation of outdoor watering systems, such as larger cities and suburbs. However, any community can benefit by some degree of managing outdoor use.

There is no immediate cost to implementing an ordinance, however, this activity will have an immediate impact on revenues and should be planned for in the budget process.

Outstanding results, ease of implementation, and growing acceptance makes twice-per-week ordinances an activity that should be given serious consideration.

Water Rate Increases

Conservation pricing and water rate increases can be used to effectively target high-volume customers, while also maintaining revenue requirements. The project recommended this activity to illustrate savings that could contribute to meeting supply volumes with low cost to the utility.

Determining the right balance and consideration to customers is an exercise unique to each individual utility. By providing savings estimates associated with this measure, utility staff can consider this benefit along with other factors that may make raising water rates the right decision.

Rain Barrels

Rain barrels are growing in popularity. They produce the lowest water savings of the four recommended activities, but they are a great first step in establishing a proactive conservation program.

The public easily understands the purpose of a rain barrel, making it an easily adopted measure for customers while also offering an opportunity to engender positive customer relations through sales, rebates, and give-away events. Vendors are plentiful and there are many ways to promote their use.

Activities Not Recommended

There are many other effective activities going on around the state that were not specifically recommend for various reasons. For example, activities that contribute to plumbing code savings are well known and quantifiable. However, these savings are going to be realized over time without any specific action by the utilities. Recommendations were made to enhance the suite of activities being employed by the utilities.

Outdoor water audits and budgets are another useful tool in a conservation program that can yield results. However, this activity requires time, money, and expertise. Most utilities do not have the ability to provide all the necessary resources for this activity. The goal of this project's recommendations was to provide suggestions that would actually be considered and eventually implemented.

The methodology and formulas provided with this report could allow utilities to explore hypothetical scenarios. Various options could be studied based on many factors including estimates of savings potential. However, that, too, is a complicated process not likely to be widely pursued.

Section 11 describes a practical way to quantify conservation activities using an easy-to-understand web-based dashboard that will make savings estimates a process that any utility could benefit from. Such a system will make it easier for utilities to design a custom-made conservation program suited to their own specifics needs and limitations.

11 Practical Method to Estimate and Measure the Implementation of Recommended Municipal Water Conservation Activities in the State Water Plan

The method used to execute this project proved to be thorough, highly detailed at the utility level, and malleable to changes along the way. However, it also proved to be time consuming for project staff and required much of participating utility's staff.

TWDB's 2012 quantification report recommended three ways that similar work could be accomplished (BBC Research and Consulting, 2012).

1. Develop consistent regional and statewide conservation savings estimates;
2. Develop a potential tool to standardize and improve provider-level water use data and conservation savings estimates; and
3. Develop a common data collection and reporting system that would create a robust database of water conservation data.

The findings of this report concur with those recommendations, but with modern updates to what can now be achieved. It is recommended that the TWDB adopt a dynamic, easy-to-use web application that streamlines these processes and:

- Combines bottom-up approaches to quantification conducted by some of the largest utilities with the top-down approaches used by states
- Makes data collection more accurate every year and eventually real-time
- Makes the water conservation state planning function based on yearly projections and able to be updated based on real savings being achieved in the field
- Instills higher confidence in conservation volumes that are being achieved every year instead of more uncertain decadal volumes being formulated every five years
- Allows the quantification process to be performed for utilities that would not be able to otherwise due to limited staff time and resources
- Because of ease of use, allows many more utilities to participate in the quantification process every year to gain a fuller picture of conservation being achieved
- Provides utilities with clear, easy-to-understand visual results related to goal achievement and tracking progress

Appendix A – Participating Utilities' Total Estimated Savings Compared to Participants' Water Management Strategies Supply Volumes

Participating Utilities' Total Estimated Savings Compared to Their Collective Conservation WMS Supply Volumes (in acre-feet per year) by Region

Terms used in Tables A1–A15:

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[1] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[1] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table A-1. **Region A Participating Utilities' Total Estimated Savings Compared to Their Collective Conservation WMS Supply Volumes (in acre-feet per year).**

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

RE: Research Contract with Averitt and Associates; Contract No. 1600012030, Draft Report Comments

DRAFT REPORT RECEIVED: July 18, 2017

Enclosed is the draft report comment letter.

Please forward to Robert E. Mace for his signature.

Thank you.

The Honorable Kip Averitt
Averitt and Associates, Inc.
1212 Guadalupe Street, Suite 301
Austin, TX 78701

RE: Research Contract with Averitt and Associates, Inc., Contract No. 1600012030, Draft Report Comments

Dear Mr. Averitt:

Staff members of the Texas Water Development Board (TWDB) have completed a review of the draft report prepared under the above-referenced contract. ATTACHMENT 1 provides the comments resulting from this review. As stated in the TWDB contract, Averitt and Associates, Inc. (Averitt) will consider revising the final report in response to comments from the Executive Administrator and other reviewers. In addition, Averitt will include a copy of the Executive Administrator's draft report comments in the Final Report.

The TWDB looks forward to receiving one (1) electronic copy of the entire Final Report in Portable Document Format (PDF) and six (6) bound double-sided copies. **Please further note, that in compliance with Texas Administrative Code Chapters 206 and 213 (related to Accessibility and Usability of State Web Sites), the digital copy of the final report must comply with the requirements and standards specified in statute. For more information, visit http://www.sos.state.tx.us/tac/index.shtml.** If you have any questions on accessibility, please contact David Carter with the Contract Administration Division at (512) 936-6079 or David.Carter@twdb.texas.gov.

Averitt shall also submit one (1) electronic copy of any computer programs or models, and, if applicable, an operations manual developed under the terms of this Contract.

Please feel free to contact Mr. John Sutton of our Conservation staff at (512) 463-7988 or john.sutton@twdb.texas.gov if you have any questions or need any further information.

Sincerely,

Robert E. Mace, Ph.D., P.G. Date: ________________
Deputy Executive Administrator
Water Science and Conservation

General Report

1. Report should read as one report, needs cover page and a table of contents.
2. Considering having an executive summary separate from the reports that describes the study, approach, etc.
3. Appendix numbering needs to be corrected.
4. The statewide report provides more in depth discussion on methodological assumptions and limitations that would be extremely beneficial to include in the RWPG and utility reports (e.g. page 9, 2nd paragraph discussion).
5. Do not round numbers. All numbers in the report text and in the footnotes should be exact.
6. Some paragraphs are spaced inconsistently with the report. IE. 6.2.2.
7. Participating Utility lists are inconsistently formatted. Some are alphabetized down-to-right and others right-to-down.
8. Many double spaces after periods in every report. Too many to list.
9. Colored columns currently serve no consistent purpose. Either color group them with related data, or make them all the same color.
10. Initial use of acronym is spelled out. Acronym should not be defined more than once (and it was, e.g. GPCD) in the short reports.
11. The "TWDB" logo/label should be removed from all pages and only a clearly worded reference to TWDB as the funding agency in response to a legislative rider should be included at the beginning of each report.
12. Methodology section of state regional and entity summaries and sources of data references and explanations is inadequate. The methodological description, including data sources, must be sufficiently detailed to allow others to replicate the study and the findings/conclusions/results. Methodology should, in clearly detail and explain what data was collected, how it was collected, how it was used to draw conclusions aimed at achieving the goals of the study.
13. The stated study goals in the state report do not match the stated study goals in the regional reports.
14. Throughout all reports, clarify whether "acre-feet" should, instead, be "acre-feet per year".
15. Reports do not adequately summarize the key assumptions used throughout the study or the technical/methodological limitations regarding the uncertainties and difficulties in attempting to quantifiably measure conservation savings that may have already been achieved.

STATE REPORT

16. Page 1, section 1.1 – describe the process of engagement. 230 utilities were targeted, only 170 participated.
17. Show the list of all participating utilities.
    - Page 2, section 1.2 – need to rework bullets 6, 6 and 8. Concerned about aggregating the activity savings vs. WMS volumes and declaring everything

fine. Potentially some big conservers can push the water-saved numbers up and it looks like plenty of water is being conserved. The problem may still exist on a regional or local level. If the volumes saved and WMS volumes are aggregated, then the state and regional reports should list the number of participating utilities that do not reach the near and long-term WMS volumes.

- Page 2, section 1.2 – last bullet – Not clear on this statement. Be clear if the 2020 Mun Cons WMS strategy volume or the 2020 Existing Supply volume is used. Similar to above, a surplus in one utility does not negate a shortage in another. SWP states 203,757 AFY in 2020 for Municipal Conservation.

18. Page 2, section 1.3, second paragraph – Need to elaborate on "The state should potentially develop a process to standardize and improve provider-level water use data and conservation savings estimates". Consider deleting the first sentence. Explain what is a robust database of water usage and how much more robust might the state be.
19. Page 2, section 1.3, last paragraph – not sure of citing BBC, 2012.
20. Page 3, section 2, first paragraph – cite should be TWDB.
    - Cite the 16 regional water plans.
    - Last sentence - Most of this sentence is a direct quote starting with "in addition", so needs to be in quotation marks and cited.
21. Page 3, section 2, second paragraph – cite source of 811,000 acre/feet and the state water plan.
22. Section 2, Paragraph 3, 3rd sentence – "Accomplishing our municipal conservation goals is critical to continuing to entice the best and brightest employers and employees to the state – and to keeping them here." This is beyond a factual statement for a report branded from TWDB.
23. Page 3, section 2, fourth paragraph – Please explain the source of these numbers, seem to be high. Also add the cost of conservation WMS. This figure includes the cost of reservoirs. See table on page 99 of 2017 SWP.
24. Page 3, section 2, last paragraph – replace" are being" to "will be".
25. Section 2.1, first paragraph, 2nd sentence – "... (Region I did not participate)…" should be rephrased as "identified utilities in Region I did not participate". Please describe outreach and communication efforts to Region I and what reason they declined. Please accurately reflect that the Region I RWPG was not asked to directly participate in the study.
26. Page 4, section 2.1 – delete second bullet.
27. Page 4, section 2.1, third bullet – replace "conservation goals" with "water management strategies".
28. Page 4, section 3 – cite TWDB.
29. Page 5, section 3.1, first bullet – Note if all targeted reductions follow this formula or not. Only region L is cited. Identify all RWPGs or none specifically that don't recommend further reductions after 140 gpcd.
    - Last paragraph – Cite the regions.
    - Avoid use of such adjectives as "venerable" in a report branded from TWDB.
30. Section 4, Table 2-1 – Suggest adding column of "Number of Invited Utilities" to illustrate opportunity provided to Region I.

31. Page 9, section 6.2, second paragraph – statement made in the last sentence needs to include considerations for other factors such as wet year, economics, etc.
32. Page 10, section 6.2.1 – add underlined subtitle's for each conservation activity that was utilized in this study.
    - Third paragraph – need complete citation for EPA; AWWA.
    - Fourth paragraph, first bullet – need to provide the stated model
        - Should at least acknowledge that price increases may not always result in continued, long-term water savings as many studies have shown that after the initial savings from increases that people revert to original use habits. Geographic location and income levels can also have an impact on whether rate increases will reduce usage levels.
        - Last sub-bullet – add citation
33. Page 11, section 6.2.2, first paragraph – need to cite the 2012 TWDB Quantitation Study
    - Indent entire block quote
34. Page 11, section 6.2.2, third paragraph – typo *there* was occasionally.
35. Page 12, section 7, first paragraph – need to cite 2017 State Water Plan. 811,000 acre-feet does not seem correct.
    - Fourth paragraph – no Table 5-1 as noted.
36. Page 17, Table 7-5 – Would be helpful to note the total number of utilities this is based on.
37. Page 18 – best not to use terms or brand names such as WaterWise or WISE Guys. Conservation Kits and Irrigation Evaluations are more appropriate for utilities not using those particular programs.
38. Page 18, last paragraph – spell out PCS.
39. Page 19, Table 8-1 – text needs to describe when and why certain conservation activities end.
40. Page 20, first paragraph – delete Far and away…
    - Second paragraph – delete undoubtedly.
    - Last paragraph should read - Forty-five of the 170 participating utilities have adopted ordinances limiting outdoor watering to twice per week and are projected to save 107,654 acre-feet in 2020. That savings estimate is 59 percent of the entire state's 2020 supply volume of 182,799 acre-feet.
41. Page 20, section 9, #2 – delete Instead.
    - Last bullet – need complete citation
    - Last sentence - delete or explain the last sentence – Of course...
42. Page 22, second paragraph – Cite TWDB 2012 Quantification Report. Be sure of complete title and use it consistently throughout the report.
    - Section 10, fourth bullet – This recommendation is unclear; explain or delete if not needed.

REGIONAL REPORTS
General

43. Section 1, second paragraph - Do not believe these were the primary goals. The scope of work has the primary goals as 1. Developing an approach to estimate the implementation of recommended strategies, 2. Assess and quantitatively determine the implementation of those strategies, and 3. Incorporate use of BMPs to meet needs.
    - Section 1.1 does not appear to describe study objectives but rather includes some disparate information and describes some tasks. For example, the first sentence refers to "first objective" but does not describe what the first objective is.
44. Section 1.2, first paragraph – need to cite State Water Plan.
45. Section 2, first paragraph, similar notes as in the state plan. Concerned about aggregating all of the numbers and then declaring success. List the number of participating utilities that will meet their 2040/2070 WMS volumes and those that will not. "Xx of the 63 utilities are not expected to achieve the WMS volumes in 2070; the average shortfall is estimated to be x,xxx."
    - There appears to be no basis provided for the Result (page 3) that Region D will be "short by 5,226 acre-feet".
    - There appears to be no numerical or methodological basis provided for the statement "The non-participating utilities of the region must achieve 148 acre-feet [sic] of WMS supply volume for municipal conservation by the end of the planning period."
46. Section 2.1, second paragraph – Need to cite plan.
    - Quote needs to be blocked and indented.
47. Section 2.1 - Please clarify the calculation of "utility population" from the 2016 regional water plans. The population projections in these plans were based upon city boundaries, not utility service areas. Sometimes these populations align in the 2016 RWPs but generally they do not (ex: DWU vs. City of Dallas). Utility service area planning will be the basis for the 2021 RWPs/2022 SWP so representation of "utility populations" from the 2016 RWPs/2017 SWP is misleading and causes confusion for the reader. If the planning groups consider the information in this report during the development of their 2021 RWP, could be unnecessarily confusing.
48. Recommend further or more robust discussion of what the "over/short" methodologies are, what the results are meant to convey, and what the limitations of the analysis are. As currently presented it is difficult to understand for the general reader and oversimplifies "over" and "short". On face value, "short" can be interpreted by the general reader as "failure to conserve" without an understanding of the limitations of the analysis or challenges to measure and achieve conservation savings on an annual basis due to a variety of factors.
49. Page 3, last paragraph - The report states that this report "should not be considered a final report". Delete this sentence entirely as it misstates to readers that, in fact, it will actually be a "final report".
50. Section 4 - Do not mention specific third-party programs by name.

51. The report states that the "Disparity Table[s]" for each utility show "how much of the change in the GPCD is due to quantifiable water conservation activities and water loss control efforts and how much from other factors" but does not acknowledge the overarching issue of the difficulty of isolating and measuring conservation in light of the many variables that impact GPCD including weather, the economy, socioeconomic factors and other variables that are not addressed in these studies. This comment also applies to the first two paragraphs on page 8.
52. Page 3, Conclusions section - Reports do not provide a clear methodological or numerical basis for the conclusions. Delete conclusions or provide detailed methodology and numerical basis for conclusions presented.
53. Page 4: descriptor headers in text to not match table headers. For example, "Utility Population" does not match the first field in Table 3-1. Correct either report text or table header naming to align.
    - The methodological and sources of numbers for the summary numbers presented in Table 3-1 are not specifically clear. Provide methodological information for the basis of the table numbers, including the year basis for each, that is in sufficient detail for others to confirm or to replicate the Table. Recommend also including description of how data from different years was used and compared.
    - The purposes and differences of the two tables, 3-1 and 3-2 are unclear in the report. Please clarify the differences and significance of the two tables.
54. Page 8, third paragraph - lists how conservation activities were quantified but does not provide any details about the numerous methodologies listed including with numbers in Table 4-1. Provide detailed methodology sufficient to replicate study results associated with each of the quantification methods listed and all numbers presented in Table 4-1.
55. Page 10 - the key assumption that "savings grow with demand" is not substantiated in the report and does not appear reasonable in light of the fact that increased demands do not necessarily translate to conservation savings especially in instances where new demand comes online at a starting lower GPCD, for example, due to new building construction etc. Please revise report accordingly.
56. Page 12 - Report does not appear to provide any factual basis for the statement "These activities are all projected to be cost effective." Provide basis for statement or delete sentence entirely.
57. Page 12, Last paragraph - The report does not appear to provide any factual basis for the conservation practices recommended for Region D. Provide basis for statement or delete sentence entirely.
58. Section 7.3 - overemphasizes the PACE program. Reduce discussion of PACE program and include more balanced discussion of other training and financing opportunities in report section.
59. Resources like AWE, the Saveteaaswater site, the best management practices, water efficiency network trainings and AWWA would be good things to include as resource options.

Region A

- Several numbers in the report are off by ±3 acre-feet per year.
- Table 3-2 differs from footnote #1.

Region C

- Denton County FWSD listed in report, but we have WUGs for #1A, #7, and #10. Only reviewed the planning data for #1A as this was the only one found on the Participating Utility Contacts list. Add the "#1A" to the name in the regional report or clarify which utilities are being used.
- Table 3-2 differs from footnote #1.

Region D

- Page 3, second to last paragraph, first sentence - The statement: "The WMS supply volume for Texarkana is particularly high." is vague and has no apparently basis in the report. Strike sentence in its entirety. Entire paragraph is difficult to understand. Rewrite remainder of paragraph.

Region E

- El Paso has roughly 1,000 acre-feet per year, which is about half, of their municipal conservation supply drop off in 2040. The report ignored this statistic.

Region H

- Huntsville is listed as a participating utility; however, it does not have any recommended WMS strategy supplies assigned to it, nor is it called out in the text as being individually invited. Thus, it seems to lack the criteria to "identify municipal conservation as a WMS in their regional water plans within the first two decades of the planning period."

Region K

- Similar issue with naming as C. Might suggest to name "Travis County" to "Travis County WCID No. 17" or clarify which utilities are being used.

Region L

- Atascosa Rural WSC's municipal conservation WMS does not take effect until 2070; therefore, does not meet the first two decade criteria.
- Table 3-1 - The water loss reduction shown as zero is confusing. SAWS perhaps did not understand that this was going to be represented in this way. SAWS has had water loss control efforts since before 2015, but this would lead a reader to think no utility in Region L was ever working on the issue.
    - Year 16 shows changes in the data. Any reduction in savings should be explained. If the conclusion was that SAWS intended to stop conservation that needs to be cleared up. SAWS' last plan may have accidentally given that impression as it only showed targets out to certain date.
- Table 3-2 - Finding this confusing. Seems to be actual data up until a certain date. Show how is the unaccounted for conservation volume is calculated. Be clear if

there are targets in Region L showing reductions and not a plan for achieving them.

- Section 4, Quantified Savings - It seems questionable to call out the WaterWise brand name for the kits. Instead show that retrofit kits were provided by either in house efforts or through a third party vendor. The program savings assumes 100 percent installation of the kits. The updated REUS study unfortunately was unable to discern significant savings from replaced showerheads and aerators. It's unclear why as in theory it should save. But replacement programs like this should include some caveats as those just learning will assume savings will be as advertised by vendor.
- Section 4, Quantified Savings - It is concerning to call out Save Water Co. as a specific strategy. This company is not active in Region L (at least not in San Antonio). Having them listed in an official report appears to endorse them and could lead to confusion, Instead perhaps list having in house or third party programs that identify and repair leaks and replace high flow fixtures.
- Section 4, Quantified Savings - WISE Guys is a great third party contractor. But it is concerning to call them out specifically in an official TWDB report. It would seem more logical to have it categorized as Third Party Irrigation Evaluation. The current language seems to imply that WISE Guys is the only endorsed way to do this. Local utilities could hire licensed irrigators to do this type of service.
- Section 6-2 – This heading and text do not seem to go together. The statement needs further explanation and backup data. Residential for small towns may be lower than more urban large communities because there may be less discretionary usage. This report was not intended to analyze this, but it would be worth noting that this is a complex issue needing further analysis. There may still be significant water savings options for small towns, but the options may be different than for other areas with different consumption patterns.

Region M

- Similar issue with naming as in Region C - Hidalgo County MUD #1.

Region P

- A prime example of Participating Utility Population matching the report when 'WugEntityPrimaryRegion' is used, but does not match with 'WugSplitRegion'.

UTILITY REPORTS

General Comments

60. Page 2: remove the use of "your" throughout report.
61. Reports do not appear logical as it appears to indirectly mix multiple, poorly labeled GPCDs "reported GPCD" "recent GPCD" – one GPCD used in the regional plan that was the basis for the WMS strategy that is also referenced in the table and at least one other GPCD that is associated with conservation reports and that will almost certainly be different than the value used in the regional water plan since the plan is a different GPCD basis for a different circumstance of drought of record. In instances where the drought of record GPCD is low, it is likely and easily predictable, without

any study, that every entity will appear to not be meeting their planned WMS conservation since one would be comparing a default low-GPCD with a wetter year GPCD. Address this issue in the report by modifying methodology.

62. The fundamental report methodology appears flawed in that is mixing conditions such as inaccurately referring to "WMS Volume as GPCD Reduction" using a resulting GPCD under non-drought conditions which will inevitably result in the appearance of not meeting a target since the DOR condition which may have a higher or lower water use and GPCD depending on the relative weather conditions on which the conservation plan reporting is based and the historic year that was selected for water planning purposes.

63. Report methodology appears fundamentally flawed in that it is making inappropriate comparisons between total water use as well as recent GPCDs reported in utility conservation plans and entirely different, and GPCDs and WMSs that are in the regional water plan and that are selected and utilized for a different purpose, that being drought of record water planning conditions in which there is often significantly different water use depending on the dry year condition selected for planning.

64. It is unclear what comparisons are being made in the tables and report. For example, it is unclear on page 1 what "their quantified savings" are and how and where they were calculated.

65. Section 1, first paragraph, first sentence – Add the complete agency name to the citation.
    - Need to cite regional water plans

66. Section 1.1 Methodology –
    - Need to cite first sentence.
    - Add to end of first paragraph - It should be noted that in comparing information from the regional water planning process, from the conservation plans and the water loss audits, and from the utility itself, some slight inconsistencies may occur. As an example, municipal water user groups that are incorporated cities in the 2017 State Water Plan have population and water demand projections limited to their city limits while information in the conservation plan, water loss audit, and from the utility itself pertains to the utility's entire service area, regardless of city limits. Report authors have attempted to minimize such discrepancies, but the nature of the planning process and various reports dictate that current efforts to quantify conservation efforts in relation to the conservation water management strategies must accept possible discrepancies at this point.
    - Third paragraph – Cite Dallas conservation plan.

67. Page 2, paragraph 3: Report does not explain the methodology used to quantify "activity savings."

68. Page 2, fourth paragraph: Sentence is unclear and the critical methodology or numerical basis that was used to arrive at "their quantified savings from activities dating back to 2012" is not presented in the report.

69. Page 2, second to last paragraph: the report does not explain the very critical and difficult step of how the contractor "quantified savings from activities dating back five years from the utility's most recent water conservation plan on file with the

TWDB." Explain, in detail, how this was performed and describe in detail the numerous limitations associated with attempting to making such estimates considering the difficulty of isolating and measuring conservation in light of the many variables that impact GPCD including weather, the economy, socioeconomic factors and other variables that are not addressed in these studies and that, based on the information provided, was not addressed in any fashion in the technical methods used by the contractor.

70. Chapters 2, Footnote 5 – the limitations presented in this footnote are significant. Recommend they be placed in the text of the report rather than as a footnote.

71. Chapter 2, Footnote 6 – Recommend identifying directly in the utility reports if the base year deviates from 2011.

72. Section 2.2, Actual Water Loss Reduction Savings (as of 2015) - Do not use the GPCD term to avoid confusion if the end result is a MG volume.
    - This definition should read: The difference between a baseline per-person per-day water loss and the most recent per-person per-day water loss value reported in the 2015 water loss audit on file with TWDB and then converted to a million gallons (MG) per year volume. The summary of these savings can be referenced in Table 4 -2.

73. Section 2.2, Conservation WMS Volume – cite regional plan.

74. Section 2.3, first paragraph, last sentence - As noted earlier, this can be a misleading comparison, comparing a dry-year (2011) RWP GPCD to a wet-year (2015) GPCD. The report must address this comparison. If the 2015 RWP GPCD is used, as posted on the TWDB website (197 for Dallas), the dry-year, wet-year comparison still needs to be noted.
    - For most entities, this should result in a large positive disparity: going from a dry-year use to a wet-year use should result in a large decrease that is not explained by conservation activities. In Dallas's case, the reduction in GPCD should have been greater, but there must have been a latent increase in per-person water use.

75. Section 2.3, Total GPCD - should read as: Year Zero in this column is the utility's baseline RWP GPCD consumption. The utility's most recently reported current Total GPCD value is carried forward in the subsequent years. Any increases or decreases to GPCD in those years would affect the savings listed in the "Annual Savings with Reduction in GPCD (MG)" and the "Difference" columns.
    - Cite source of this GPCD.
    - Again concerned this compares the 2011 RWP GPCD with a 2015 Total GPCD (from conservation plan annual report).

76. Table 2-3, Disparity column - Don't understand the assumption that the 2015 GPCD would be carried forward in to the future; GPCD values jump all over the place. Consider an analysis between the baseline RWP GPCD and the 2015 RPW GPCD, reducing the table to 2 rows: Baseline and 2015.

77. Section 2.4, Table 2-4 - The description of the column headings should be clearly stated as in sections 2.1 – 2.3, even if that means repeating the same information again.

78. Section 2.5, Table 2-5 - The description of the column headings should be clearly stated as in sections 2.1 – 2.3, even if that means repeating the same information again.
79. Section 2.5 – The basis for numbers developed in entire section is not clear. Provided specific sources of data and make clearer what was reported from Dallas vs what was calculated and where assumptions came from.
80. Section 2.5, fourth paragraph - is somewhat confusing, please clarify.
81. Section 2.5, fifth paragraph - Avoid using the GPCD term unless necessary. Consider removing the per-person values if they are simply going to be converted to MG volumes.
82. Section 3.1.1, AMI system – need to rethink this savings based on each utility's use.
83. Section 3.1.2, Twice a week watering – Citation, be clear if this is the Hermitte and Mace report. If so, should state that. If not, you do not have a different report referenced on the reference sheet for Hermitte.
    - Cite Sierra Club-Lone Star Chapter and the National Wildlife Federation
84. Section 5 - Data sources and methodology behind Figure 5-1 is unclear. The figure appears to present several GPCDs but only labels one line as "GPCD". It is unclear as to what "WMS volume" represents or how that was calculated.
85. Figure 5-1: What appears to be presented as a 'trend line' in Figure 5-1 is too short to draw conclusions as suggested in the paragraph above the figure. Simple, short-term GPCD trend lines are not actually a reliable indicator of conservation achievements without further analysis since there are many factors that affect GPCD and the data used to calculate GPCD and on which the trend lines are based. Please modify description in report to acknowledge that estimating/evaluating conservation savings that have actually been achieved is extremely difficult and impacted by many variables impacting GPCD.
86. Section 6, Suggested Activities – Recommendations need to have an explanation on why the utility should consider this activity and how those savings were calculated.
87. Section 7 - Should only include references for those cited in the text of each report.
    - Spell out all abbreviations.
    - Alphabetize list.
    - When the same author, use same initials. Also, should mention that the references should be the same throughout, so if using initials stay with initials, but if using full name, use full name for all.
88. Remove comments like "Keep up the good work".

Brushy Creek Municipal District

89. It reads that by 2070 the RWP expects Brushy Creek to reduce volume by 669 MG through conservation strategies. This does not seem possible since the total volume in 2016 was 940 MG and the district will not be any bigger in 2070 than now.

City Of Dallas

90. Clarify if this should be the City of Dallas or Dallas Water Utility in heading, text and citations.
91. Report is difficult to follow and understand. For example, the statement in the second paragraph on page 7: "Table 2-3 shows the disparity between all current

quantified activities and the savings represented by the decline from your utility's 2011 baseline total GPCD in the regional water plan and currently reported GPCD levels." Talks about a single "disparity" (presented in Table 2-3) but refers to three different numbers that confuse the reader. And, again, the reference and comparison between current GPCD and the drought of record GPCD for the purposes of quantifying a "disparity" is inappropriate since the basis for the two GPCDs are different and could likely and predictably bias the analysis throughout.

92. No basis is provided for recommending rainwater harvesting on page 19. Strike recommendation.
93. Page 19: strike bullet #4.

City of Sweetwater

94. It is unclear if these suggestions are tailored to Sweetwater (each utility) or are universal suggestions for all utilities.
95. Explain how are the quantified savings are derived. Explain the metrics used to measure quantified savings and if the metrics are standardized between utilities.
96. Explain how the quantified savings are derived and if it is from a statewide compilation or from what utilities have reported on their annual reports. Explain if there is a standardized methodology required for use by each utility to measure quantified savings. If not, then the tendency will be for utilities to over-report quantified savings and the comparison of actual savings by each utility will come up short when compared to projected savings.

Intentionally Left Blank

Appendix D - Regional Reports

Statewide Municipal Water Conservation Quantification Project
Report to the Panhandle Water Planning Group
Region A • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region A make up approximately 275,000 in population by 2020, which is 66 percent of the region's total projected 2020 population.
- Participating utilities make up 61 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of six participating water utilities in place—and without further enhancement—Region A as a whole is projected to fall short of its recommended 2020 water conservation supply volume by 1,151 acre-feet per year.
- With the current conservation activities of six participating water utilities in place—and without further enhancement—these utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 278 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2070 supply volume by 585 acre-feet per year.
- Of those utilities surveyed, the region averages 2.3 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies (WMS) that can be used to meet the needs identified throughout the 50-year planning period.

Region A is a 21-county region encompassing the upper Panhandle of Texas. It is a sparsely populated, agricultural region in which municipal conservation plays a relatively smaller role than in other regions.

The Region A Plan states, "[w]ater conservation is a valued water management strategy in the Panhandle Water Planning Group (PWPG) because it helps prolong the limited water resources in the region." The plan calls for 5,429 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this water management strategy supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.
[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region A are 3,690 acre-feet per year for 2020, 4,022 acre-feet per year for 2030, 4,333 acre-feet per year for 2040, 4,675 acre-feet per year for 2050, and 5,044 acre-feet per year for 2060.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region A, seven utilities met these criteria and were contacted for participation. Six utilities accepted and were included in the results:

Amarillo	Dalhart
Borger	Dumas
Canyon	Perryton

These utilities represent approximately 66 percent of the 2020 population of Region A and represent 61 percent of the 2020 WMS supply volume for municipal water conservation for the region.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Meeting Recommended Supply Volumes

The PWPG considered the following criteria when recommending conservation strategies to WUGs within the region:

- Cost
- Potential Water Savings
- Time to Implement
- Public Acceptance
- Technical Feasibility
- Staff Resources

Published reports and previous studies were used to estimate savings of water conservation BMPs. It was noted by the planners that water savings from some BMPs were difficult to estimate because there is little supporting data available for them (Texas Water Development Board, 2016).

Region A planners selected these strategies (activities) for utilities in Region A:

- Education and Outreach – assumed savings would be 2 percent of total water demand
- Water Audits and Leak Repair – assumed 20 percent of entities' losses could be recovered

- Rate Structure – assumed that 10 percent of households would save 6,000 gallons annually
- Landscape Ordinance – assumed savings of 1,000 gallons per increased number of households annually for utilities over 20,000 population
- Time of Day Watering Limit – assumed that 75 percent of the population would realize 1,000 gallons/household per year for utilities over 20,000 population
- Water Waste Ordinance – assumed savings of 3,000 gallons/household/year for 75 percent of households.

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region A. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region A.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
A	6	5	0	0	0	0	1	1	0	1	0	14	2.3

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How can conservation activity be measured accurately on a large scale to ensure Region A is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[4] for that year.[5] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[6] for water loss GPCD[7] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred

---

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[5] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[6] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water rate increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). The project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings quantified by the utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

Accelerated plumbing code savings (PCS)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.
Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility’s service area are implemented on a micro-scale is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting its Municipal Conservation Supply Volumes?

The 2016 Region A Water Plan recommends that Region A should achieve 5,429 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the six utilities surveyed in this region are estimated to exceed their portion (3,534 acre-feet per year) by 585 acre-feet per year by 2070. The non-participating municipal WUGs have a WMS supply volume for municipal conservation of 1,895 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the six participating utilities. These utilities constitute approximately 66 percent of the region's population and account for 61 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[8] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

2069	1,882	2,203	4,085	3,507	0	3,507	578
2070	1,898	2,222	4,120	3,534	0	3,534	585

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
A	Meeting	4	985	4	1,079	4	1,206	4	1,335	4	1,468	4	1,614
	Not Meeting	2	(707)	2	(770)	2	(835)	2	(898)	2	(961)	2	(1,029)
	Total Region A	6	278	6	309	6	371	6	437	6	507	6	585

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volume for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	761	1,287	2,047	1,640	407
2016	1,111	1,300	2,410	2,051	360

2069	1,882	2,203	4,085	5,391	(1,306)
2070	1,898	2,222	4,120	5,429	(1,309)

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[10] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

---

[10] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

2070	2,221	1,884						9			6		4,120

9 Region A Challenges

Listed below are challenges the PWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt. Traditional conservation activities, therefore, are not seen as particularly necessary.

By educating these communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could develop a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the PWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The PWPG should educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The PWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in future similar data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential for further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in the region are considering AMI systems. AMI systems are a popular and growing activity throughout the state. They represent a new way of informing consumers about their consumption patterns and can be a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and PWPG could help those communities take advantage of new technology. Meters must be replaced over time and AMI systems could help many municipalities reduce staff overhead along with their water-savings benefits. Perhaps the PWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs. Note that SWIFT funding is only available for projects that are recommended in a utility's regional water plan.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region A, the most common suggested activities were to install AMI to help reduce water loss and inform customers about their water use patterns and to use periodic, strategic water rate increases to reduce consumption.

See Section 9 in the State Report that is part of this document for an extended discussion on these suggested activities and why they were chosen.

Statewide Municipal Water Conservation Quantification Project
Report to the B Water Planning Group • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

> **Task 1**: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 2**: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 3**: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.
>
> **Task 4**: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.
>
> **Task 5**: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 6**: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- The participating utility in Region B makes up approximately 107,000 in population by 2020, which is 52 percent of the region's total projected 2020 population.
- The participating utilities make up 90 percent of the region's recommended 2020 municipal conservation goal (supply volume).
- With the current conservation activities of the participating water utility in place—and without further enhancement—Region B as a whole is projected

to exceed its recommended 2020 water conservation supply volume by 473 acre-feet per year.

- These conservation savings estimates will fall short of the region's 2059 supply volume by 21 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of the participating water utility in place—and without further enhancement—this utility is projected to exceed its recommended 2020 water conservation supply volume by 961 acre-feet per year.[1]
- Without further activity, this utility is projected to exceed its 2070 supply volume by 1,362 acre-feet per year.
- The participating utility employs four measurable conservation activities to achieve these results.

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region B is comprised of ten entire counties and a portion of one county in north central Texas. In general, most of the population is concentrated in eastern portions of the region with over one-half located in and around Wichita Falls. The City of Wichita Falls is the largest water demand center in the region. The region is generally arid and not a rapid growth area of the state.

The Region B Plan states, "[w]ater conservation is a valued water management strategy in Region B because it helps extend the water resources in the region. It is recommended for all municipal and irrigation water users, whether the user has a defined shortage or not." The plan calls for 6,098 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016a). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this water management supply volume for municipal water conservation.

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region B are 4,972 acre-feet per year for 2020, 5,160 acre-feet per year for 2030, 5,182 acre-feet per year for 2040, 5,446 acre-feet per year for 2050, and 5,810 acre-feet for 2060 per year.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region B, no utilities met these criteria; however, it was important to include Region B in the statewide research project. Wichita Falls agreed to participate.

Wichita Falls represents approximately 52 percent of the 2020 population of Region B and 90 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Wichita Falls received a report on the results of its water conservation activities and water loss efforts and is included as a part of this report. This report summarizes the savings from the individual utility report within Region B.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing

- Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Meeting Recommended Supply Volumes

The regional planners noted the work of the Water Conservation Task Force. They believe however, that regional planning groups should be allowed to establish goals for the region only after "…sufficient data on water use have been collected using consistent data reporting requirements."

The Region B Water Planning Group (RBWPG) recommended these municipal conservation strategies:

- Leak Detection, Repair and Pipeline Replacement – assumed to save 2,242 acre-feet per year by 2070
- Public Education Programs
- Water Waste Ordinance (permanent time-of-day and day-of-week restrictions for outdoor watering)
- Landscape Ordinance requiring low-water use landscapes for new residential construction

The last three strategies (activities) are expected to save an additional 2,242 acre-feet per year by the end of the planning period. Savings estimates are based on what other North Texas communities are saving, and upon savings achieved by El Paso, Austin, and San Antonio. Also, it was assumed that water systems with per capita demand over 100 gallons per capita per day (GPCD) could save 10 percent through advanced conservation and utilities with under 100 GPCD could save five percent through the end of the planning period.

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the City of Wichita Falls. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region B.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
B	1	1	1	0	0	0	0	0	0	0	1	4	4.0

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

> *How can conservation activity be measured accurately to ensure Region B is meeting the marks set out in its regional water plan?*

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare GPCD consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[4] for that year.[5] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[6] for water loss GPCD[7] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized

---

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[5] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[6] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

<u>Savings Quantified by the Utility</u>

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

<u>Accelerated Plumbing Code Savings (PCS)</u>

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections

for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may

create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Region B Water Plan recommends that Region B should achieve 6,098 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that Wichita Falls is estimated to exceed its portion (4,484 acre-feet per year) by 1,362 acre-feet per year by 2070. The non-participating municipal WUGs have a WMS supply volume for municipal conservation of 1,614 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region’s participating utility’s quantified savings estimates are progressing toward meeting its 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the one participating utility. This utility constitutes approximately 52 percent of the region’s population and account for 90 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[8] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

2062	3,638	2,140	5,778	4,484	0	4,484	1,294
2063	3,643	2,143	5,787	4,484	0	4,484	1,303
2064	3,649	2,146	5,795	4,484	0	4,484	1,311
2065	3,654	2,150	5,804	4,484	0	4,484	1,320
2066	3,659	2,153	5,812	4,484	0	4,484	1,328
2067	3,665	2,156	5,820	4,484	0	4,484	1,336
2068	3,670	2,159	5,829	4,484	0	4,484	1,345
2069	3,675	2,162	5,837	4,484	0	4,484	1,353
2070	3,680	2,165	5,846	4,484	0	4,484	1,362

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole. As there is only one participating utility in this region, the table shows Wichita Falls' decadal surpluses.

Table 7-2. Participating Utilities Estimated To Be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
B	Meeting	1	961	1	1,056	1	1,125	1	1,186	1	1,277	1	1,362
	Not Meeting		0		0		0		0		0		0
	Total Region B	1	961	1	1,056	1	1,125	1	1,186	1	1,277	1	1,362

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volume for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	3,290	1,915	5,205	2,210	2,996
2016	3,292	1,919	5,211	2,762	2,449

2070	3,680	2,165	5,846	6,098	(252)

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[10] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[10] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

9 Region B Challenges

Listed below are challenges the RBWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Regarding the smaller towns in Region B that did not participate, their success in meeting WMS supply volume will depend on their understanding of the need for, and value of, municipal conservation. They should understand their part in the region's WMS supply volume objectives.

Educating these communities on their portion of the regional WMS supply volume for municipal water conservation objectives would encourage them to work toward achieving reasonable results.

9.3 State Prisons

State prisons are a large user of water. However, they are not always required to adhere to drought restrictions or conservation measures. This issue came to light during the 2011 drought when Wichita Falls was desperate for water.

10 Recommendations

Listed below are recommendations for the RBWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The RBWPG should educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something very specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The RBWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in future similar data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities around the state are considering Advanced Metering Infrastructure (AMI). AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and RBWPG could help those communities take advantage of new technology. Meters must be replaced over time and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the RBWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would allow for the calculation of savings and cost estimates for Wichita Falls.

Regarding Region B, Wichita Falls should continue to expand its use of AMI with the customer portal that is has recently deployed.

See Section 9 in the State Report that is part of this document for an extended discussion on these suggested activities and why they were chosen.

Statewide Municipal Water Conservation Quantification Project
Report to the Region C Water Planning Group • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

> **Task 1**: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 2**: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 3**: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.
>
> **Task 4**: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.
>
> **Task 5**: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 6**: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region C make up approximately 6,100,000 in population by 2020, which is 81 percent of the region's total projected 2020 population.
- Participating utilities make up 90 percent of the region's recommended 2020 municipal conservation goal (supply volume).
- With the current conservation activities of 63 participating water utilities in place—and without further enhancement—Region C as a whole is projected

to exceed its recommended 2020 water conservation supply volume by 65,432acre-feet per year.

- With the current conservation activities of 63 participating water utilities in place—and without further enhancement—these utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 70,994 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2070 supply volume by 75,846 acre-feet per year.
- Of those utilities surveyed, the region averages 3.4 per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region C covers all or part of 16 North Central Texas counties. As of the 2010 census, the population of Region C represents 25 percent of Texas' total population. Region C is heavily urbanized, with 83 percent of the population located in cities with populations in excess of 20,000 people. Region C is a rapidly growing part of the state.

The Region C Plan states, "[c]ities and utilities in Region C have made significant strides in the implementation of water conservation efforts. It is important that suppliers in the region build on this momentum with continued conservation efforts." The plan calls for 131,056 acre-feet per year of savings to come from municipal water conservation by 2070.[2] Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.
[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region C are 55,628 acre-feet per year for 2020, 88,259 acre-feet per year for 2030, 97,327 acre-feet per year for 2040, 109,091 acre-feet per year for 2050, and 120,028 acre-feet per year for 2060.

interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region C, 89 utilities met these criteria and were contacted for participation. Out of the 89, 63 utilities accepted and were included in the results:

Addison	Denton Cty. FWSD #1A	Irving	Sardis-Lone Elm
Allen	Desoto	Kaufman	Seagoville
Arlington	Duncanville	Keller	Sherman
Balch Springs	East Fork SUD	Lancaster	Southlake
Bonham	Euless	Little Elm	Springtown
Carrollton	Farmers Branch	Mabank	Terrell
Cedar Hill	Forney	McKinney	The Colony
Cockrell Hill	Fort Worth	Mesquite	Tioga
Colleyville	Frisco	Midlothian	Trophy Club
Copeville SUD	Garland	Mountain Peak SUD	University Park
Coppell	Grand Prairie	North Richland Hills	Van Alstyne
Corinth	Grapevine	Plano	Watauga
Corsicana	Haltom City	Richardson	Weatherford
Crowley	Highland Park	Rockwall	Wortham
Dallas	Highland Village	Sachse	Wylie
Denton	Hurst	Saginaw	

These utilities represent about 82 percent of the 2020 population of Region C and represent 90.1 percent of the 2020 WMS supply volume for municipal water conservation for the region.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Meeting Recommended Supply Volumes

In deriving recommended conservation strategies for Region C, the Region C Water Planning Group (RCWPG) considered cost, potential waste savings, and the prospects of implementation. They also took into account current implementation levels.

Recommendations are for implementation by each water user group in the region and include:

- Enhanced Education – savings were estimated to be two percent by 2070
- Rate Structures – savings were estimated to be two percent by 2070
- Enhanced water loss control – savings were projected to be .05 percent by 2020
    - Audits
    - Active leak detection and repair
    - Pressure control
    - Water main replacement
    - AMR technology
- Time of Day Irrigation Restrictions – savings were assumed to be 2.9 percent of seasonal water demands for customers with automatic irrigation systems, and

- Water Waste Prohibition – savings were estimated to be 3.3 percent of irrigation water use for accounts with automatic irrigation systems.

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region C. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities Of Participating Utilities (Since 2011) In Region C.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
C	63	49	31	3	6	3	14	3	5	6	30	213	3.4

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How conservation activity be measured accurately to ensure Region B is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to simply compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[4] for that year.[5] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[6] for water loss GPCD[7] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

---

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).
[5] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.
[6] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of survey several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings Quantified by The Utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed uniform savings estimates used throughout the project for other utilities tracked closely with their internal savings figures.

Accelerated Plumbing Code Savings (Pcs)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility’s service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Region C Water Plan recommends that Region C should achieve 131,056 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the 63 utilities surveyed in this region are estimated to exceed their portion (105,568 acre-feet per year) by 75,846 acre-feet per year by 2070. The non-participating municipal WUGs have a WMS supply volume for municipal conservation of 25,488 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the 63 participating utilities. These utilities constitute approximately 82 percent of the region's population and account for 90.1 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[8] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from all Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in Acre-Feet Per Year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
C	Meeting	52	72,947	50	58,509	47	68,854	45	74,606	42	78,587	43	84,588

	Total Region C	63	70,994	63	55,720	63	63,088	63	66,807	63	71,104	63	75,846

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

<u>Total Savings from All Conservation Activity for Participating Utilities</u> – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

<u>Total Regional WMS Volume</u> – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

<u>Unaccounted for Conservation WMS Volume</u> – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	80,840	18,700	99,540	24,724	74,817

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[10] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[10] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (In Acre-Feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rain Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

9 Region C Challenges

Listed below are challenges the RCWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that many utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in smaller towns throughout Texas is very low. Traditional conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in small and medium-sized towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt.

By educating these communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could develop a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the RCWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The RCWPG should educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something very specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The RCWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in similar future data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in Region C are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and RCWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the RCWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region C, the most commonly suggested activities were to install AMI with a customer portal to help reduce water loss and inform customers about their water use patterns and to use periodic, strategic water rate increases to reduce consumption. Rain barrels would be also effective in some parts of the region. And although Region C has a high incidence of twice-a-week watering ordinances, there is still plenty of opportunity to save significant amounts of water through wider adoption of this activity.

See Section 9 in the State Report that is part of this document for an extended discussion on these suggested activities and why they were chosen.

Statewide Municipal Water Conservation Quantification Project
Report to the North East Texas Regional Water Planning Group
Region D • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- The participating utility in Region D makes up approximately 37,000 in population by 2020, which is five percent of the region's total projected 2020 population.
- The participating utility makes up 99 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of the participating water utility in place—and without further enhancement—Region D as a whole is projected to fall short of its recommended 2020 water conservation supply volume by 4,976 acre-feet per year.
- These conservation savings estimates will fall short of the region's 2070 supply volume by 5,374 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of the participating water utility in place—and without further enhancement—this utility is projected to fall short of its recommended 2020 water conservation supply volume by 4945 acre-feet per year.[1]
- Without further activity, this utility is projected to fall short of its 2070 volume by 5,226 acre-feet per year.
- The participating utility employs two measurable conservation activities to achieve these results.

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region D is made up of all or part of 19 counties in North East Texas. The North East Texas Region is largely rural. Most towns within the region have populations of less than 10,000 people and there are many small, unincorporated areas within counties. Region D is not a rapid-growth area of the state.

The plan calls for 6,876 acre-feet per year of savings to come from municipal water conservation by 2070 [2] (Texas Water Development Board, 2016c). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

It is important to note that the WMS supply volume for Texarkana is particularly high. Per the Region D water plan:

> "For each water user group with a shortage and consumption greater than 140 gallons per capita per day (GPCD), a water conservation strategy was considered.... After

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region D are 6,434 acre-feet per year for 2020, 6,717 acre-feet per year for 2030, 6,884 acre-feet per year for 2040, 6,836 acre-feet per year for 2050, and 6,848 acre-feet per year for 2060.

evaluation, the advanced water conservation scenario was only considered as an applicable strategy for a single municipality, the City of Texarkana, whereby savings of up to approximately 6,815 [sic][3] ac-ft/yr were determined. These amounts are significant due to abnormally high per capita usage developed by TWDB from reported 2011 usage. The conservation savings are adequate to alleviate the shortage for Texarkana, pending development of the proposed new water treatment facility to replace existing infrastructure" (Texas Water Development Board, 2015c).

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region D, one utility met these criteria, Texarkana. The leadership at this utility accepted the invitation to participate in the study.

Texarkana represents nearly five percent of the 2020 population of Region D and represents 99.5 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Texarkana received a report on the results of its water conservation activities and water loss effortsand is included as a part of this report. This report summarizes the savings from the individual utility report within Region D.

4 Regional planning group approach to municipal water conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water

[3] The value listed for Texarkana in the written text of the Region D Water Plan is actually 6,815 ac-ft/yr. The Interactive State Water Plan has a value of 6,728 acre-feet per year by 2070.

Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Determining Supply Volumes

The Region D planners recommended 140 GPCD[4] as the threshold for determining to which WUGs conservation strategies should apply. The target 140 GPCD was selected to match the recommendation of the State Water Conservation Implementation Task Force. Cost effectiveness is the overriding criteria when evaluating water conservation strategies (Texas Water Development Board, 2016e).

[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

4.2 Approach to Meeting Recommended Supply Volumes

The North East Texas Regional Water Planning Group (NETRWPG) identified one entity within the region to which advanced conservation strategies should apply—the City of Texarkana. Advanced conservation strategies recommended by the planning group are:

- Single-family Clothes Washer Rebates
- Single-family Irrigation Audits
- Single-family Rainwater Harvesting
- Single-family Rain Barrels
- Multi-family Clothes Washer Rebates
- Multi-family Irrigation Audits
- Multi-family Rainwater Harvesting
- Commercial Clothes Washer Rebates (coin-operated)
- Commercial Irrigation Audits
- Commercial Rainwater Harvesting

Savings from these strategies "…are adequate to alleviate the shortage for Texarkana…"

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the City of Texarkana. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (Since 2011) in Region D.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
D	1	0	0	1	0	0	0	0	0	0	0	2	2.0

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

> *How can conservation activity be measured accurately to ensure Region D is meeting the marks set out in its regional water plan?*

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities re being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[5] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[6] for that year.[7] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the

---

[5] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[6] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[7] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

difference between each individual utility's baseline[8] for water loss GPCD[9] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

---

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings Quantified by the Utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

Accelerated Plumbing Code Savings (PCS)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting its Municipal Conservation Supply Volumes?

Table 7-1 shows how the region's participating utility's quantified savings estimates are progressing toward meeting its 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the one participating utility. This utility constitutes approximately five percent of the region's population and account for 99.5 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation activity savings for participating utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water loss reduction savings (as of 2015) for participating utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total savings from all conservation activity for participating utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS volume for participating utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water loss reduction WMS volume for participating utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total yearly WMS volume for participating utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (In Acre-Feet Per Year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

2069	321	1,181	1,502	6,728	0	6,728	(5,226)
2070	321	1,181	1,502	6,728	0	6,728	(5,226)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole. As there is only one participating utility in this region, the table shows Texarkana's' decadal shortfalls.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
D	Meeting		0		0		0		0		0		0
	Not Meeting	1	(4,945)	1	(5,169)	1	(5,311)	1	(5,240)	1	(5,227)	1	(5,226)
	Total Region D	1	(4,945)	1	(5,169)	1	(5,311)	1	(5,240)	1	(5,227)	1	(5,226)

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from all Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	317	1,132	1,449	2,860	(1,410)
2016	317	1,133	1,451	3,574	(2,124)
2017	318	1,135	1,453	3,574	(2,122)
2018	318	1,136	1,454	4,289	(2,835)
2019	319	1,137	1,456	5,004	(3,548)
2020	319	1,138	1,458	6,434	(4,976)
2021	320	1,142	1,461	6,462	(5,001)
2022	320	1,145	1,465	6,491	(5,026)
2023	321	1,148	1,469	6,519	(5,050)
2024	321	1,151	1,472	6,547	(5,075)
2025	322	1,155	1,476	6,576	(5,099)
2026	322	1,158	1,480	6,604	(5,124)
2027	323	1,161	1,484	6,632	(5,149)
2028	323	1,164	1,487	6,660	(5,173)
2029	324	1,167	1,491	6,689	(5,198)
2030	324	1,171	1,495	6,717	(5,222)
2031	324	1,172	1,496	6,734	(5,238)
2032	324	1,173	1,497	6,750	(5,254)
2033	324	1,174	1,497	6,767	(5,270)
2034	324	1,175	1,498	6,784	(5,285)
2035	324	1,176	1,499	6,801	(5,301)
2036	324	1,177	1,500	6,817	(5,317)
2037	324	1,178	1,501	6,834	(5,333)
2038	324	1,179	1,502	6,851	(5,348)
2039	324	1,180	1,503	6,867	(5,364)
2040	323	1,181	1,504	6,884	(5,380)
2041	323	1,181	1,504	6,879	(5,375)
2042	323	1,181	1,504	6,874	(5,371)
2043	323	1,181	1,504	6,870	(5,366)
2044	323	1,181	1,503	6,865	(5,361)
2045	323	1,181	1,503	6,860	(5,357)
2046	322	1,181	1,503	6,855	(5,352)
2047	322	1,181	1,503	6,850	(5,348)
2048	322	1,181	1,503	6,846	(5,343)
2049	322	1,181	1,503	6,841	(5,338)
2050	322	1,181	1,502	6,836	(5,334)
2051	322	1,181	1,502	6,837	(5,335)
2052	322	1,181	1,502	6,838	(5,336)
2053	322	1,181	1,502	6,840	(5,337)
2054	321	1,181	1,502	6,841	(5,339)
2055	321	1,181	1,502	6,842	(5,340)
2056	321	1,181	1,502	6,843	(5,341)
2057	321	1,181	1,502	6,844	(5,342)
2058	321	1,181	1,502	6,846	(5,344)
2059	321	1,181	1,502	6,847	(5,345)
2060	321	1,181	1,502	6,848	(5,346)
2061	321	1,181	1,502	6,851	(5,349)
2062	321	1,181	1,502	6,854	(5,352)
2063	321	1,181	1,502	6,856	(5,354)
2064	321	1,181	1,502	6,859	(5,357)
2065	321	1,181	1,502	6,862	(5,360)
2066	321	1,181	1,502	6,865	(5,363)
2067	321	1,181	1,502	6,868	(5,366)
2068	321	1,181	1,502	6,870	(5,368)
2069	321	1,181	1,502	6,873	(5,371)
2070	321	1,181	1,502	6,876	(5,374)

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[12] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-Home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

aerators, toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from most widely used conservation activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity
2015	1,132			317									1,449
2016	1,133			317									1,451

9 Region D Challenges

Listed below are challenges the NETRWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

Utilities often do not know what their role is regarding regional conservation supply volumes. It will be important to continue to monitor and communicate progress on the WMS supply volume.

10 Recommendations

Listed below are recommendations for the NETRWPG and utilities.

10.1 Participation And Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The NETRWPG should educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them

something very specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The NETRWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in future similar data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities around the state are considering Advanced Metering Infrastructure. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and NETRWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the NETRWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess” a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

Region D should consider implementing twice a week watering ordinances, deployment of AMI with customer portal, strategic water rate increases and rain barrels as cost effective means to advance municipal conservation. Details were supplied in the report to Texarkana.

See Section 9 in the State Report that is part of this document for an extended discussion on these suggested activities and why they were chosen.

Statewide Municipal Water Conservation Quantification Project
Report to the Far West Texas Water Planning Group
Region E • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region E make up approximately 770,000 in population by 2020, which is 80 percent of the region's total projected 2020 population.
- Participating utilities make up 88 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of two participating water utilities in place—and without further enhancement—Region E as a whole is projected to exceed its recommended 2020 water conservation supply volume by 13,275 acre-feet per year.
- With the current conservation activities of two participating water utilities in place—and without further enhancement—these two utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 13,527 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2070 supply volume by 13,954 acre-feet per year.
- Of those utilities surveyed, the region averages four activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region E encompasses the most arid region of the State of Texas. The seven-county region lies within the Rio Grande River Basin. With the exception of El Paso County, the counties of far West Texas are among the least populated in the State. Region E is not considered a rapid growth region.

The Region E Plan states, "[w]ater conservation is one of the most important components of water supply management. Recognizing its impact, setting realistic goals, and aggressively enforcing implementation, may significantly extend the time when new supplies and associated infrastructure are needed." The plan calls for 6,408 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016d). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region E are 2,159, acre-feet per year for 2020, 2,449 acre-feet per year for 2030, 1,539 acre-feet per year for 2040, 2,972 acre-feet per year for 2050, and 5,991 acre-feet per year for 2060.

(shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region E, two utilities met these criteria and were contacted for participation. Horizon Regional MUD accepted and participated in the study. In order to get a fuller picture of savings occurring in Region E, the City of El Paso (El Paso Water) also agreed to participate.

These two utilities represent 80 percent of the 2020 population of Region E and 88 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Each of the participating utilities received a report on the results of its water conservation activities and water loss efforts. This report summarizes the savings from the individual utility reports within Region E.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Meeting Recommended Supply Volumes

Quantity, reliability, and cost were the criteria considered when recommending water conservation strategies for Region E. Savings were not estimated for each individual strategy. Planners expect to reduce demand by about three GPCD per decade (Texas Water Development Board, 2016d)

The Far West Texas Water Planning Group (FWTWPG) group recommends three strategies to be implemented by the utilities within the region:

- Reuse of treated wastewater
- Water loss audit and main-line repair
- Public education

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region E. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region E.

Region	Water Loss Reduction	Water Rate Increases	3x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
E	2	0	2	0	0	0	0	0	0	1	3	8	4.0

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How can conservation activity be measured accurately to ensure Region E is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[4] for that year.[5] Thus, quantifying from 2012 and forward is the most accurate way

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process

to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[6] for water loss GPCD[7] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility’s baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

---

divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[5] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[6] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.

- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

<u>Savings Quantified by the Utility</u>

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

<u>Accelerated Plumbing Code Savings (PCS)</u>

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain

> volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting its Municipal Conservation Supply Volumes?

The 2016 Far West Texas Water Plan recommends that Region E should achieve 6,408 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The participating utilities' portion of this recommended supply volume is 6,009 acre-feet per year. The results of this study indicate that Region E is estimated to exceed its recommended supply volume by an estimated 13,954 acre-feet per year by 2070. The non-participating municipal WUGs have a WMS supply volume for municipal conservation of 399 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the two participating utilities. These utilities constitute approximately 80 percent of the region's population and account for 88 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[8] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

---

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
E	Meeting	1	13,875	1	14,056	1	15,980	1	15,661	1	13,796	1	14,489
	Not Meeting	1	(348)	1	(332)	1	(338)	1	(408)	1	(473)	1	(535)
	Total Region E	2	13,527	2	13,724	2	15,642	2	15,253	2	13,323	2	13,954

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	12,825	(1,243)	11,582	960	10,623
2016	16,770	(1,262)	15,508	1,199	14,308

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[10] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

3x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to three times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[10] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	3x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity
2015	(1,243)	0	6,044								1,774	5,008	11,582

2068	(2,219)	9,144	9,364								1,774	1,696	19,759
2069	(2,238)	9,203	9,427								1,774	1,696	19,861
2070	(2,258)	9,262	9,490								1,774	1,696	19,963

9 Region E Challenges

Listed below are challenges the FWTWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- The study found that smaller utilities in El Paso County were acutely aware of the need for and value of municipal conservation. For the most part, they follow the lead of El Paso.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in small towns throughout West Texas is relatively low. Traditional municipal conservation activities, therefore, are not seen as particularly necessary.

By educating these communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could develop a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the FWTWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The FWTWPG could educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. For this project, each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The FWTWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in similar future data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities around the state are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and FWTWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the FWTWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE

offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess” a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region E, the most common suggested activities were to install AMI with a customer engagement portal to help reduce water loss and inform customers about their water use patterns and to use periodic, strategic water rate increases to reduce consumption.

Statewide Municipal Water Conservation Quantification Project
Report to the Region F Regional Water Planning Group • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region F make up approximately 400,000 in population by 2020, which is 57 percent of the region's total projected 2020 population.
- Participating utilities make up 58 percent of the region's recommended 2020 municipal conservation goal (supply volume).
- With the current conservation activities of 10 participating water utilities in place—and without further enhancement—Region F as a whole is projected to

exceed its recommended 2020 water conservation supply volume by 2,739 acre-feet per year.

- With the current conservation activities of 10 participating water utilities in place—and without further enhancement—these 10 utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 4,566 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2070 supply volume by 6,662 acre-feet per year.
- Of those utilities surveyed, the region averages 1.8 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region F is a 32-county area of West Texas. It is a sparsely populated, agricultural region with a heavy oil and gas presence. Although it is not a rapidly growing region, it is prone to population fluctuations due to the volatility of the oil and gas industry.

The Region F Plan states, "[w]ater conservation is a potentially feasible water savings strategy that can be used to preserve the supplies of existing water resources. For municipalities and manufacturers, advanced drought planning and conservation can be used to protect their water supplies and increase reliability during drought conditions." The plan calls for 6,183 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016e). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

---

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region F are 4,344 acre-feet per year for 2020, 4,765 acre-feet per year for 2030, 5,115 acre-feet per year for 2040, 5,477 acre-feet per year for 2050, and 5,817 acre-feet per year for 2060.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region F, 14 utilities met these criteria and were contacted for participation. Out of the 14, 10 utilities accepted and were included in our results:

Andrews	Midland
Ballinger	Odessa
Brady	San Angelo
Coleman	Snyder
Junction	Winters

These utilities represent 57 percent of the 2020 population of Region F and 58 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Each of the participating utilities received a report on the results of its water conservation activities and water loss efforts. This report summarizes the savings from the individual utility reports within Region F.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Meeting Recommended Supply Volumes

The Region F Water Planning Group (RFWPG) considered the following criteria when recommending conservation strategies to the WUGs within the region (Texas Water Development Board, 2016e):

- Cost
- Potential Water Savings
- Time to Implement
- Public Acceptance
- Technical Feasibility
- Staff Resources

Published reports and previous studies were used to estimate savings of the BMPs. The planners noted that water savings for some BMPs were difficult to estimate because there is a lack of sufficient data.

Selected strategies for utilities in Region F:

- Education and Outreach – assumed savings would be two percent of total water demand
- Water Audits and Leak Repair – assumed 20 percent of entities losses could be recovered

- Rate Structure – assumed that 10 percent of households would save 6,000 gallons annually
- Landscape Ordinance – assumed savings of 1,000 gallons per increased number of households annually for utilities over 20,000 population
- Time-of-Day Watering Limit – assumed that 75 percent of the population would realize 1,000 galloons/household per year for utilities over 20,000 population
- Water Waste Ordinance – assumed savings of 3,000 gallons/household/year for 75 percent of households.

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region F. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region F.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
F	10	7	1	0	0	0	0	0	0	0	0	18	1.8

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How can conservation activity be measured accurately on a large scale to ensure Region F is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, our approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[4] for that year.[5] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[6] for water loss GPCD[7] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).
[5] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.
[6] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings Quantified by the Utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

Accelerated Plumbing Code Savings (PCS)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into our estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited our ability to collect full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Region F Water Plan recommends that Region F should achieve 6,183 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the 10 utilities surveyed in this region are estimated to exceed their portion (3,941 acre-feet per year) by 6,662 acre-feet per year by 2070. Non-participating municipal WUGs have a WMS supply volume for municipal conservation of 2,242 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the 10 participating utilities. These utilities constitute approximately 57 percent of the region's population and account for 58 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[8] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

<u>Total Savings from All Conservation Activity for Participating Utilities</u> – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

<u>Conservation WMS Volume for Participating Utilities</u> – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

<u>Water Loss Reduction WMS Volume for Participating Utilities</u> – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

<u>Total Yearly WMS Volume for Participating Utilities</u> – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

<u>Over (Short)</u> – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

the WMS volume, it will appear in parentheses.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
F	Meeting	5	5,039	5	5,457	5	5,882	5	6,365	5	6,895	5	7,441

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	2,324	1,757	4,080	1,931	2,150
2016	4,798	1,746	6,544	2,413	4,130
2017	5,233	1,735	6,967	2,413	4,554
2018	5,282	1,724	7,005	2,896	4,109
2019	5,330	1,713	7,043	3,379	3,664
2020	5,379	1,703	7,083	4,344	2,739

2069	7,855	2,668	10,523	6,146	4,377
2070	7,911	2,691	10,603	6,183	4,420

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[10] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[10] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity
2015	1,757	1,008	1,316										4,079
2016	1,746	3,469	1,330										6,543
2017	1,735	3,890	1,343										6,968
2018	1,724	3,925	1,356										7,007

2067	2,629	5,906	1,837										10,371
2068	2,649	5,951	1,847										10,447
2069	2,668	5,997	1,858										10,523
2070	2,691	6,042	1,869										10,602

9 Region F Challenges

Listed below are challenges the RFWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in small towns throughout West Texas is relatively low. Traditional municipal conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt.

By educating these communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could develop a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the RFWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The RFWPG should educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The RFWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in similar future data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in Region F are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and RFWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the RFWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region F, the most common suggested activities were to install AMI with a customer engagement portal to help reduce water loss and inform customers about their water use patterns and to use periodic, strategic water rate increases to reduce consumption.

Statewide Municipal Water Conservation Quantification Project
Report to the Brazos G Water Planning Group
Region G • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

> **Task 1**: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 2**: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 3**: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.
>
> **Task 4**: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.
>
> **Task 5**: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 6**: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region G make up approximately 1,000,000 in population by 2020, which is 45 percent of the region's total projected 2020 population.
- Participating utilities make up 73 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of 22 participating water utilities in place—and without further enhancement—Region G as a whole is projected to fall short of its recommended 2020 water conservation supply volume by 993 acre-feet per year.
- These conservation savings estimates will fall short of the region's 2070 supply volume by 76,881 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of 22 participating water utilities in place—and without further enhancement—these 22 utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 1,890 acre-feet per year.[1]
- Without further activity, these utilities are projected to fall short of their 2022 supply volume by 658 acre-feet per year.
- Of those utilities surveyed, the region averages 2.8 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region G is comprised of all or portions of 31 counties. The area has diverse characteristics that make for a wide variation in water supplies, demands, and availability.

The Brazos G Regional Water Plan states, "[c]onservation in the 2016 Plan is much more aggressively considered than in the 2011 Plan." The plan calls for 96,816 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016f). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.
[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region G are 10,632 acre-feet per year for 2020, 29,914 acre-feet per year for 2030, 46,634 acre-feet per year for 2040, 63,775 acre-feet per year for 2050, and 81,301 acre-feet per year for 2060.

(shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region G, 21 utilities met these criteria and were contacted for participation. All 21 utilities accepted and were included in the results. The City of Waco was also added because it is such a large utility for the region. Below are the 22 participating utilities:

Abilene	Hewitt
Bethesda WSC	Kempner WSC
Brenham	Lampasas
Brushy Creek MUD	Leander
Bryan	Possum Kingdom WSC
Burleson	Robinson
Cedar Park	Round Rock
Chisholm Trail SUD	Sweetwater
College Station	Temple
Georgetown	Waco
Groesbeck	Woodway

These utilities represent approximately 45 percent of the 2020 population of Region G and represent 73 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Each of the participating utilities received a report on the results of its water conservation activities and water loss efforts. This report summarizes the savings from the individual utility reports within Region G.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Determining Supply Volumes

In general, the conservation WMS supply volumes for municipal WUGs reflect a one percent annual reduction in gallons per capita per day (GPCD) until a target of 140 GPCD[3] is reached. More aggressive targets were set for some WUGs in Williamson County.

[3] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

4.2 Approach to Meeting Recommended Supply Volumes

The Brazos G Water Planning Group (BGWPG) recommended achieving conservation goals by using BMPs identified by the Water Conservation Task Force:

- System Water Audit and Water Loss
- Water Conservation Pricing
- Prohibition on Wasting Water
- Showerhead, Aerator, and Toilet Flapper Retrofit
- Residential Toilet Replacement Programs with Ultra-Low-Flow Toilets
- Residential Clothes Washer Incentive Program
- School Education
- Water Survey for Single-Family and Multi-Family Customers
- Landscape Irrigation Conservation and Incentives
- Water-Wise Landscape Design and Conversion Programs
- Athletic Field Conservation
- Golf Course Conservation
- Metering of all New Connections and Retrofitting of Existing Connections
- Wholesale Agency Assistance Programs
- Conservation Coordinator
- Reuse of Reclaimed Water
- Public Information
- Rainwater Harvesting and Condensate Reuse
- New Construction Graywater
- Park Conservation
- Conservation Programs for Industrial, Commercial, and Institutional Accounts.

Savings for these recommendations were not estimated individually, but rather a broad approach was used with guidance from the Task Force and the Texas Commission on Environmental Quality (TCEQ). Savings from landscape irrigation is expected to save 11 GPCD and public education is projected to save three GPCD.

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region G. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region G.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
G	21	13	2	2	4	1	1	5	1	4	4	58	2.8

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How can conservation activity be measured accurately on a large scale to ensure Region G is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[4] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[5] for that year.[6] Thus, quantifying from 2012 and forward is the most accurate way

[4] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[5] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process

to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[7] for water loss GPCD[8] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

---

divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[6] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[7] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.

- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

<u>Savings Quantified by the Utility</u>

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

<u>Accelerated Plumbing Code Savings (PCS)</u>

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain

volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Brazos G Regional Water Plan recommends that Region G should achieve 96,816 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the 22 participating utilities are estimated to meet goals through 2020. By 2070 these utilities' current savings are estimated to be short of the recommended supply volumes by 50,189 acre-feet per year.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the 22 participating utilities. These utilities constitute approximately 45 percent of the region's population and account for 73 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

<u>Total Savings from All Conservation Activity for Participating Utilities</u> – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

2069	13,523	6,180	19,703	69,163	7	69,170	(49,467)
2070	13,646	6,289	19,935	70,117	7	70,124	(50,189)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
G	Meeting	11	6,364	6	3,927	5	3,968	4	3,434	4	3,976	4	4,557
	Not Meeting	10	(4,474)	15	(14,780)	16	(25,691)	17	(36,426)	17	(46,950)	17	(54,737)
	Total Region G	21	1,890	21	(10,853)	21	(21,723)	21	(32,992)	21	(42,974)	21	(50,189)

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	3,978	1,355	5,333	4,725	608

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[11] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[11] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

9 Region G Challenges

Listed below are challenges the BGWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in small towns throughout the region is very low. Traditional conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt.

By educating these communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could develop a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the BGWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The BGWPG should educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something very specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The BGWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in future similar data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in Region G are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and BGWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the BGWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE

offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region G, the most common suggested activities were to install AMI with customer engagement portals to help reduce water loss and inform customers about their water use patterns and to use periodic, strategic water rate increases to reduce consumption. The implementation of twice-per-week watering restrictions also have the potential to save large quantities of water with relatively low overhead cost for utilities.

See Section 9 in the State Report that is part of this document for an extended discussion on these suggested activities and why they were chosen.

Statewide Municipal Water Conservation Quantification Project
Report to the Region H Water Planning Group • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

> **Task 1**: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 2**: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 3**: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.
>
> **Task 4**: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.
>
> **Task 5**: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 6**: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region H make up approximately 3,300,000 in population by 2020, which is 45 percent of the region's total projected 2020 population.
- Participating utilities make up 62 percent of the region's recommended 2020 municipal conservation goal (supply volume).
- With the current conservation activities of 21 participating water utilities in place—and without further enhancement—Region H as a whole is projected

to exceed its recommended 2020 water conservation supply volume by 18,761 acre-feet per year.

- These conservation savings estimates will fall short of the region's 2027 supply volume by 433 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of 21 participating water utilities in place—and without further enhancement—these 21 utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 26,489 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2037 supply volume by acre-feet per year, but will fall short of their 2070 volume by 34,962 acre-feet per year.
- Of those utilities surveyed, the region averages 3.1 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region H encompasses all or part of 15 counties in southeast Texas and includes the majority of the San Jacinto River Basin and the lower reaches of the Brazos and Trinity River Basins. The area is generally characterized by urbanized land use and broad-based economic development. In areas outside of the urban core, agriculture dominates economic activity. Large numbers of municipal utility districts (MUDs) also make this region unique.

The Region H Plan states, "[w]ater conservation has always been a key component of the Region H Water Planning Group (RHWPG). For the development of the 2016 [Regional Water Plan], the RHWPG expanded municipal conservation to consider both water loss reduction and the application of other advanced methods in addition to the baseline conservation applied by TWDB." The plan calls for 150,660 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016g). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

---

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region H are 20,364 acre-feet per year for 2020, 49,637 acre-feet per year for 2030, 78,442 acre-feet per year for 2040, 107,062 acre-feet per year for 2050, and 129,016 acre-feet per year for 2060.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region H, 33 utilities met these criteria and were contacted for participation. Out of the 33, 14 utilities accepted and were included in the results. In order to get a more accurate scope of conservation data, Deer Park, Friendswood, Galveston, Huntsville, Pearland, Stafford (Fort Bend County WCID #2), The Woodlands, and Lake Jackson were also included. Below are the participating utilities:

Baytown	Humble	Pearland
Clute	Huntsville	Southern Montgomery Cty. MUD
Conroe	Jersey Village	Stafford
Deer Park	Katy	Sugarland
Friendswood	Lake Jackson	The Woodlands
Galveston	League City	West University Place
Houston	Pasadena	Willis

These utilities represent approximately 45 percent of the 2020 population of Region H and represent 62 percent of the 2020 WMS supply volume for municipal water conservation for the region.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more

- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Meeting Recommended Supply Volumes

"Region H focuses much of its conservation resources towards outreach, conservation rates, and water system audits, leak detection, and repair" (Texas Water Development Board, 2016g).

The Region H planners incorporated a "bottom-up" study into its approach to estimate potential savings from advanced conservation activities. By doing so, the plan noted that if ordinances limiting outdoor watering to twice per week (or less) were implemented, that measure alone could produce enough savings to meet supply volumes well into the planning period.

Advanced water conservation strategies recommended in the Region H Plan include:

- Residential high-efficiency toilet rebates for single-family households

- Residential low-flow showerhead replacement for single-family households
- Kitchen pre-rinse spray valve replacement for commercial-industrial-institutional customers
- Cooling tower modifications for commercial-industrial-institutional customers
- Tank-type high-efficiency toilet replacement for commercial-industrial-institutional customers
- Large landscape water budgets for commercial-industrial-institutional or single-family customers

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region H. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region H.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
H	21	10	2	4	1	15	3	3	3	2	2	66	3.1

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How can conservation activity be measured accurately on a large scale to ensure Region H is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[4] for that year.[5] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[6] for water loss GPCD[7] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility’s baseline.

---

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[5] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[6] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings Quantified by the Utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

Accelerated Plumbing Code Savings (PCS)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting its Municipal Conservation Supply Volumes?

The 2016 Region H Water Plan recommends that Region H should achieve 150,660 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the 21 utilities surveyed in this region are estimated to achieve recommended supply volumes through the year 2038. Beyond that, they will need to employ sufficient activities to cover the 34,962 acre-feet per year deficit that will accrue by the year 2070. The non-participating municipal WUGs have a recommended WMS supply volume for municipal conservation of 62,970 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the 21 participating utilities. These utilities constitute approximately 45 percent of the region's population and account for 62 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[8] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

---

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

2069	30,686	21,715	52,401	51,647	34,891	86,538	(34,137)
2070	30,875	21,853	52,728	52,590	35,100	87,690	(34,962)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)

	Total Region H	21	26,489	21	11,222	21	(3,309)	21	(17,868)	21	(26,681)	21	(34,962)

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	18,599	15,344	33,944	9,051	24,893
2016	20,632	15,479	36,110	11,313	24,797

2067	30,310	21,439	51,749	144,167	(92,418)
2068	30,498	21,577	52,075	146,331	(94,256)
2069	30,686	21,715	52,401	148,496	(96,095)
2070	30,875	21,853	52,728	150,660	(97,932)

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[10] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[10] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

9 Region H Challenges

Listed below are challenges the RHWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group that specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.
- There are hundreds of MUDs within Region H. The project struggled to establish an efficient communication link with MUD boards of directors. It will be crucial in the future to include this large population in studies and implementation efforts in order to meet the regional WMS supply volume for municipal conservation.

9.2 Teamwork and Accomplishment

There are many utilities within Region H that are unaware of their portion of the recommended WMS supply volume for municipal conservation. There is a general feeling among wholesale water customers of the City of Houston that any effort they make would be insignificant compared to the city's efforts.

By educating these communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could develop a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the RHWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The RHWPG could educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. For this project, each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The RHWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in similar future data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in the Region H are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and RHWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the RHWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region H, the most common suggested activities were to install AMI with customer engagement portals to help reduce water loss and inform customers about their water use patterns. Use of periodic, strategic water rate increases to reduce consumption is an ongoing effective activity. Twice-per-week watering ordinances also have the potential for large savings in this region.

Statewide Municipal Water Conservation Quantification Project
Report to the Plateau Regional Water Planning Group
Region J • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

> **Task 1**: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 2**: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 3**: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.
>
> **Task 4**: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.
>
> **Task 5**: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 6**: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region J make up approximately 60,000 in population by 2020, which is 43 percent of the region's total projected 2020 population.
- Participating utilities make up 74 percent of the region's recommended 2020 municipal conservation goal (supply volume).
- With the current conservation activities of two participating water utilities in place—and without further enhancement—Region J as a whole is projected to

exceed its recommended 2020 water conservation supply volume by 1,046 acre-feet per year.

- With the current conservation activities of two participating water utilities in place—and without further enhancement—these two utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 1,137 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2070 supply volume by 1,598 acre-feet per year.
- Of those utilities surveyed, the region averages 1.5 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region J is a five-county area that stretches from the Central Texas Hill Country westward to the Rio Grande River. It is a sparsely populated, arid, agricultural region. It is not considered a rapid-growth area of Texas.

The Region J Plan states, "[w]ater conservation is one of the most important components of water supply management. Recognizing its impact, setting realistic goals, and aggressively enforcing implementation may significantly extend the time when new supplies and associated infrastructure are needed." The plan calls for 358 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016h). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

---

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region J are 357 acre-feet per year for 2020, 357 acre-feet per year for 2030, 357 acre-feet per year for 2040, 358 acre-feet per year for 2050, and 358 acre-feet per year for 2060.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region J, no WUGs met the criteria. In order to gain valuable insight about water conservation in Region J, Del Rio and Kerrville were contacted, agreed to participate and were included in the results.

These utilities represent approximately 43 percent of the 2020 population of Region J and 74 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Each of the participating utilities received a report on the results of its water conservation activities and water loss efforts. This report summarizes the savings from the individual utility reports within Region J.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When

WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Meeting Recommended Supply Volumes

Water conservation strategies recommended in the Region J Plan include:

- Water loss audits
- Public education
- Brush management
- Rainwater harvesting (as an alternate strategy)

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region J. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region J.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
J	2	1	0	0	0	0	0	0	0	0	0	3	1.5

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

> *How can conservation activity be measured accurately to ensure Region J is meeting the marks set out in its regional water plan?*

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

GPCD[4] for that year.[5] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[6] for water loss GPCD[7] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility’s baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

---

[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[5] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[6] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.

- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings Quantified by the Utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

Accelerated Plumbing Code Savings (PCS)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Plateau Region Water Plan recommends that Region J should achieve 358 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the two utilities surveyed in this region are estimated to exceed their portion (266 acre-feet per year) by 1,598 acre-feet per year. The non-participating municipal WUG have a WMS supply volume for municipal conservation of 92 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region’s participating utilities’ quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the two participating utilities. These utilities constitute approximately 43 percent of the region’s population and account for 74 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[8] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole..

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
J	Meeting	1	1,461	1	1,559	1	1,657	1	1,758	1	1,853	1	1,948
	Not Meeting	1	(324)	1	(330)	1	(337)	1	(343)	1	(345)	1	(350)
	Total Region J	2	1,137	2	1,229	2	1,320	2	1,415	2	1,508	2	1,598

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	138	1,189	1,327	159	1,168

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[10] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

---

[10] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

2070	1,718	146											1,864

9 Region J Challenges

Listed below are challenges the PWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in small towns throughout rural Texas is very low. Traditional conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt. Region J has shown that small towns can make a big difference. The successes of the two participating utilities are a model for other small towns throughout Texas.

By educating communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could have a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the Plateau Regional Water Planning Group (PRWPG) and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The PRWPG should educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something very specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The PRWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in future similar data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities throughout the state are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and PRWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the PRWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region J, the most common suggested activities were to install AMI with a customer engagement portal to help reduce water loss and inform customers about their water use patterns and to use periodic, strategic water rate increases to reduce consumption.

Statewide Municipal Water Conservation Quantification Project Report to the Lower Colorado Regional Water Planning Group Region K • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region K make up approximately 1,200,000 in population by 2020, which is 72 percent of the region's total projected 2020 population.
- Participating utilities make up 84 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of eight participating water utilities in place—and without further enhancement—Region K as a whole is projected to fall short of its recommended 2020 water conservation supply volume by 7,316 acre-feet per year.
- These conservation savings estimates will fall short of the region's 2037 supply volume by 395 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of eight participating water utilities in place—and without further enhancement—these eight utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 12,448 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2070 volume by 6,207 acre-feet per year.
- Of those utilities surveyed, the region averages 7.1 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region K consists of all or part of 14 counties roughly consistent with the Lower Colorado River Basin. This is a rapidly growing area that stretches from Central Texas to the Gulf Coast.

The Region K Plan states, "[t]he LCRWPG supports conservation as an important component of water planning. It is more effective and less costly to use less water than to develop new sources." The plan calls for 86,222 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016i). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need

---

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region K are 31,253 acre-feet per year for 2020, 41,444 acre-feet per year for 2030, 52,373 acre-feet per year for 2040, 62,803 acre-feet per year for 2050, and 73,719 acre-feet per year for 2060.

(shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region K, 10 utilities met these criteria and were contacted for participation. In order to gain valuable insight about water conservation in Region K, Austin was contacted and also agreed to participate. Ultimately, eight utilities accepted and were included in the results:

Austin	Llano
Aqua WSC	Pfugerville
Horseshoe Bay	Travis County WCID #17
Johnson City	West Travis Cty. Public Utility Agency

These utilities represent approximately 72 percent of the 2020 population of Region K and 84 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Note that Leander and Cedar Park receive a substantial portion of their water supply from Region K sources; however, due to regional water planning area boundaries, they are substantially located within Region G Planning Area (Texas Water Development Board, 2015f). Thus, these two participating utilities results are included in the Region G report for this project. See Section 6 for more information on how population and WMS supply volume splits were addressed.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use

- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Determining Supply Volumes

To develop WMS supply volumes for conservation, the Region K planners started with targeted goals of 140 GPCD[3] for WUGs within the region. Rates of reduction varied from one percent per year for utilities that had a 2020 GPCD of over 200, and .05 percent per year for those under 200 GPCD (Texas Water Development Board, 2016i)

4.2 Approach to Meeting Recommended Supply Volumes

The Lower Colorado Regional Water Planning Group (LCRWPG) recommends the following conservation strategies (activities):

- Utility water loss and repair initiatives

[3] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

- "Smart" meters and AMI
- Customer behavioral engagement software
- Twice-a-week watering
- Landscape standards for new development
- Landscape irrigation evaluations
- Public outreach and education
- TCEQ 344 landscape irrigation standards for new development

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region K. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region K.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
K	8	5	6	2	4	1	0	3	0	4	24	57	7.1

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

> *How can conservation activity be measured accurately on a large scale to ensure Region K is meeting the marks set out in its regional water plan?*

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[4] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[5] for that year.[6] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[7] for water loss GPCD[8] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred

[4] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[5] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[6] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[7] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

<u>Savings Quantified by the Utility</u>

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

<u>Accelerated Plumbing Code Savings (PCS)</u>

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the colletion of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Lower Colorado Regional Water Plan recommends that Region K should achieve 86,222 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the eight utilities surveyed in this region are estimated to exceed their portion (59,305 acre-feet per year) by 6,207 acre-feet per year by 2070. The non-participating municipal WUGs for the region have a WMS supply volume for municipal conservation of 26,917 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the eight participating utilities. These utilities constitute approximately 72 percent of the region's population and account for 84 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

<u>Total Savings from All Conservation Activity for Participating Utilities</u> – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

<u>Conservation WMS Volume for Participating Utilities</u> – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

<u>Water Loss Reduction WMS Volume for Participating Utilities</u> – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

<u>Total Yearly WMS Volume for Participating Utilities</u> – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

<u>Over (Short)</u> – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
K	Meeting	4	14,513	2	17,241	2	19,681	2	21,587	2	23,320	2	25,358

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

<u>Total Savings from All Conservation Activity for Participating Utilities</u> – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

<u>Total Regional WMS Volume</u> – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

<u>Unaccounted for Conservation WMS Volume</u> – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	26,749	(3,088)	23,661	13,890	9,771

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[11] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[11] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

9 Region K Challenges

Listed below are challenges the LCRWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

It became apparent through field interviews with utility staff that not all utilities were aware of impending shortages in the region, or of their portion of the WMS supply volume for municipal conservation. There is a heightened awareness in the Central Texas area, probably due to the influence of the City of Austin. However, the awareness wanes further toward the coast.

By educating communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could have a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the LCRWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The LCRWPG should educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something very specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The LCRWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in future similar data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in Region K are considering Advanced Metering Infrastructure (AMI). AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and LCRWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the LCRWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region K, the most common suggested activities were to install AMI with a customer engagement portal component to help reduce water loss and inform customers about their water use patterns. Other suggestions included continuing to use periodic, strategic water rate increases to reduce consumption. Rain barrels are more effective in Region K than in many other regions of the state and are used successfully by some in this region. Twice-per-week watering ordinances could save many utilities large amounts of water in this region, as well.

10.5 Assistance from Wholesale Water Providers

Wholesale Water Provider (WWPs) are uniquely positioned to encourage conservation and achieve actionable results. These entities set water purchase rates and form water delivery contracts—two instances that provide opportunities to introduce conservation incentives. They have a direct interest in conserving as their water systems are expected to shoulder the burden of rapidly increasing populations and water demand. WWPs can also easily carry out district or system-wide conservation initiatives that can be easily adopted by cities with lesser resources.

The TWDB's Water Conservation Advisory Council recently adopted BMP that outlines this purpose and forward-thinking WWPs, such as Lower Colorado River Authority (LCRA), are already advancing this concept.

Here are several ways mentioned that WWPs can assist their customers with conservation:

- WWP conduct yearly water conservation plan implementation surveys to monitor progress of individual customer plan implementation and to quantify water savings from implementation of customer programs where possible.
- Develop a tracking system to track technical assistance and outreach activities
- Development of model water conservation plans and drought contingency plans that could be adopted by WWP customers
- Assistance to customers developing their own water conservation plans and drought contingency plans.
- Researching and providing advice on how to implement specific conservation programs or measures (Texas Water Development Board, 2013a)

In Region K, LCRA in particular has been instrumental in providing wholesale customers access to a variety of rebate and education programs, as well as dedicating WWP staff to monitoring and facilitating conservation throughout the authority's footprint.

Statewide Municipal Water Conservation Quantification Project Report to the South Central Texas Regional Water Planning Group Region L • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region L make up approximately 2,100,000 in population by 2020, which is 71 percent of the region's total projected 2020 population.
- Participating utilities make up 77 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of 11 participating water utilities in place—and without further enhancement—Region L as a whole is projected to fall short of its recommended 2020 water conservation supply volume by 2,672 acre-feet per year.
- These conservation savings estimates will fall short of the region's 2070 supply volume by 82,327 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of 11 participating water utilities in place—and without further enhancement—these 11 utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 2,759 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2027 supply volume by 149 acre-feet per year.
- Of those utilities surveyed, the region averages 5 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

The South Central Texas Region includes all or part of 21 counties. It ranges from arid south Texas to the Gulf of Mexico. It is a rapidly growing region with a wide range of economies and life styles.

The Region L Plan states, "[t]he South Central Texas Regional Water Planning Group (SCTRWPG) strongly supports water conservation, and for the 2016 Regional Water Plan has recommended [multiple] municipal water conservation water management strategies." The plan calls for 97,947 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016j). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify

---

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region L are 23,426 acre-feet per year for 2020, 26,804 acre-feet per year for 2030, 32,188 acre-feet per year for 2040, 49,505 acre-feet per year for 2050, and 74,125 acre-feet per year for 2060.

municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region L, 17 utilities met these criteria and were contacted for participation. Out of the 17, 11 utilities accepted and were included in the results:

Alamo Heights	San Antonio Water System
Atascosa Rural WSC	San Marcus
Crystal Clear WSC	Universal City
Hondo	Uvalde
New Braunfels	Victoria
Sabinal	

These utilities represent 71 percent of the 2020 population of Region L and represent 71 percent of the 2020 WMS supply volume for municipal water conservation for the region.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Determining Supply Volumes

To develop WMS supply volumes for municipal conservation, Region L used a target of 140 GPCD,[3] as recommended by the Water Conservation Implementation Task Force. The objective of recommended BMPs is to reduce demand by one percent per year for WUGs over 140 GPCD, and by .25 percent per year for WUGs under 140 GPCD (Texas Water Development Board, 2016j).

4.2 Approach to Meeting Recommended Supply Volumes

SCTRWPG recommends the following conservation strategies (activities) for Region L:

- Low-flow plumbing fixtures
- Water efficient appliances
- Landscape Restrictions
- Repair plumbing and water-using appliances for leaks
- Modification of personal behavior that controls the use of plumbing fixtures appliances, and lawn watering methods

[3] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region L. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region L.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
L	11	7	0	0	2	1	0	2	0	5	27	55	5.0

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How can conservation activity be measured accurately on a large scale to ensure Region L is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[4] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[5] for that year.[6] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[7] for water loss GPCD[8] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized was to use the most complete water loss data possible, which was represented by the

[4] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[5] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[6] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[7] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

<u>Savings Quantified by the Utility</u>

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

<u>Accelerated Plumbing Code Savings (PCS)</u>

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections

for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may

create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 South Central Texas Regional Water Plan recommends that Region L should achieve 97,947 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the 11 utilities surveyed in this region are estimated to exceed their portion of the regional WMS supply volume for municipal conservation through the year 2027. Without further action, these utilities are estimated to have a deficit of 51,526 acre-feet per year by 2070. The non-participating municipal WUGs have a WMS supply volume for municipal conservation of 30,801 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region’s participating utilities’ quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the 11 participating utilities. These utilities constitute approximately 71 percent of the region’s population and account for 77 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings For Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (As Of 2015) For Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings From All Conservation Activity For Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume For Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume For Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume For Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared To Participants' Conservation WMS Supply Volumes (In Acre-Feet Per Year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)
2015	12,952	4,953	17,905	7,998	0	7,998	9,907
2016	15,031	4,999	20,031	9,997	0	9,997	10,034
2017	15,570	5,046	20,616	9,997	0	9,997	10,619

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
L	Meeting	6	4,157	5	929	4	4,142	3	245	3	181	1	95
	Not Meeting	5	(1,398)	6	(4,066)	7	(8,351)	8	(15,879)	8	(35,338)	10	(51,621)
	Total Region L	11	2,759	11	(3,137)	11	(4,209)	11	(15,634)	11	(35,157)	11	(51,526)

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	12,952	4,953	17,905	10,412	7,493

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[11] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[11] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

2047	6,694	2,813									1,436	2,944	13,888
2048	6,746	2,837									1,436	2,944	13,964
2049	6,798	2,861									1,436	2,944	14,040
2050	6,849	2,885									1,436	2,944	14,116
2051	6,898	2,911									1,436	2,944	14,191
2052	6,947	2,937									1,436	2,944	14,265
2053	6,996	2,963									1,436	2,944	14,340
2054	7,045	2,988									1,436	2,944	14,415
2055	7,094	3,014									1,436	2,944	14,490
2056	7,143	3,040									1,436	2,944	14,564
2057	7,192	3,066									1,436	2,944	14,639
2058	7,241	3,091									1,436	2,944	14,714
2059	7,290	3,117									1,436	2,944	14,788
2060	7,339	3,143									1,436	2,944	14,863
2061	7,389	3,169									1,436	2,944	14,939
2062	7,438	3,195									1,436	2,944	15,014
2063	7,488	3,221									1,436	2,944	15,090
2064	7,538	3,247									1,436	2,944	15,166
2065	7,587	3,273									1,436	2,944	15,242
2066	7,637	3,299									1,436	2,944	15,317
2067	7,686	3,326									1,436	2,944	15,393
2068	7,736	3,352									1,436	2,944	15,469
2069	7,785	3,378									1,436	2,944	15,544
2070	7,835	3,404									1,436	2,944	15,620

9 Region L Challenges

Listed below are challenges the SCTRWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in small towns throughout rural Texas is very low. Traditional municipal conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt.

By educating communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could have a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the SCTRWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The SCTRWPG could educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something specific for which to strive. Additionally, these utilities should be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report as part of this project that provided general recommendations about how to move forward with municipal conservation activities.

The SCTRWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in similar data collection projects in the future. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities around the state are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and SCTRWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the SCTRWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region L, the most common suggested activities were to install AMI with a customer engagement portal component to help reduce water loss and inform customers about their water use patterns, and the continued use of periodic, strategic water rate increases to reduce consumption. Some parts of the region would benefit from the use of rain barrels and some areas could see high water savings by passing twice-per-week watering ordinances.

Statewide Municipal Water Conservation Quantification Project
Report to the Rio Grande Regional Water Planning Group
Region M • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region M make up approximately 1,200,000 in population by 2020, which is 59 percent of the region's total projected 2020 population.
- Participating utilities make up 62 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of 15 participating water utilities in place—and without further enhancement—Region M as a whole is projected to fall short of its recommended 2020 water conservation supply volume by 465 acre-feet per year.
- These conservation savings estimates will fall short of the region's 2070 supply volume by 109,552 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of 15 participating water utilities in place—and without further enhancement—these 15 utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 2,073 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2022 supply volume by 75,107 acre-feet per year.
- Of those utilities surveyed, the region averages 1.8 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region M is an eight-county area stretching from the middle of the Rio Grande River to the Gulf of Mexico. There is a shift toward urbanization and diversification of the economy, but agriculture still plays a major role in the region. Region M is rapidly growing part of the state.

The Region M Plan states, "[a]dvanced water conservation is recommended for every municipal water user group (WUG) in Region M." It further states, "[w]ater conservation is typically a non-capital intensive alternative that any water supply entity can and should pursue." The plan calls for 122,557 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016k). This volume *does not include* supply volumes from irrigation district conservation.[3] Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region M are 27,701 acre-feet per year for 2020, 47,769 acre-feet per year for 2030, 70,351 acre-feet per year for 2040, 105,847 acre-feet per year for 2050, and 135,800 acre-feet per year for 2060.

[3] Recommended volumes from irrigation district-related conservation are slated to come from existing surplus. This differs from all other regions in the state, which classify municipal water conservation as a demand reduction measure.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region M, 24 utilities met these criteria and were contacted for participation. In order to gain valuable insight about water conservation in Region M, the City of Laredo was also included. Out of the 24 invitations, 15 utilities accepted and were included in the results:

Aqua SUD	Olmito WSC
East Rio Hondo WSC	Pharr
Edinburg	San Juan
Hidalgo Cty. MUD 1	Sharyland WSC
Laredo	Union WSC
McAllen	Weslaco
Mission	Zapata Cty. Waterworks
North Alamo WSC	

These utilities represent approximately 59 percent of the 2020 population of Region M and 62 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Each of the participating utilities received a report on the results of its water conservation activities and water loss efforts. This report summarizes the savings from the individual utility reports within Region M.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Determining Supply Volumes

To develop WMS supply volumes for municipal conservation, Region M planners used a target of 140 GPCD,[4] as recommended by the Water Conservation Implementation Task Force. The objective of recommended BMPs is to reduce demand by one percent per year for WUGs over 140 GPCD, and by 0.5 percent per year for WUGs under 140 GPCD.

---

[4] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

In addition, "[t]he yield of Advanced Water Conservation, or the amount of water conserved in each decade, is the difference between the Per Capita Water Use and the Base Per Capita Goal, converted to acre-feet/year" (Texas Water Development Board, 2016k).

4.2 Approach to Meeting Recommended Supply Volumes

The Rio Grande Regional Water Planning Group (RGRWPG) recommends the following conservation strategies for Region M:

- System Operations
- Landscaping
- Education and Public Awareness
- Rebate, Retrofit, and Incentive Programs
- Conservation Technology (Includes Rainwater Harvesting)
- Regulatory Enforcement

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region M. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region M.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
M	15	9	0	1	0	1	0	0	0	1	0	27	1.8

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

> *How can conservation activity be measured accurately on a large scale to ensure Region M is meeting the marks set out in its regional water plan?*

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[5] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[6] for that year.[7] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the

[5] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[6] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[7] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

difference between each individual utility's baseline[8] for water loss GPCD[9] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

---

[8] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

6.2.1 *Caveats to specific activity savings*

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings Quantified by the Utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

Accelerated Plumbing Code Savings (PCS)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Rio Grande Regional Water Plan recommends that Region M should achieve 122,557 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. 50,441 acre-feet per year in 2070 are to be supplied by non-traditional irrigation district-related conservation that is slated to come from existing surplus. This volume is not considered in this report as municipal conservation.

The results of this study indicate that the 15 utilities surveyed in this region are estimated to exceed their portion of the recommended supply volume through the year 2023. If no other actions are taken, they are estimated to accrue a deficit of 75,107 acre-feet per year of their portion of the regional supply volume (88,112 acre-feet per year) by the end of the planning period. Non-participating municipal WUGs have a WMS supply volume for municipal conservation of 34,445 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the 15 participating utilities. These utilities constitute approximately 59 percent of the region's population and account for 62 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
M	Meeting	11	4,751	7	4,071	4	3,308	1	206	0	0	0	0
	Not Meeting	4	(2,678)	8	(9,615)	11	(20,144)	14	(34,128)	15	(53,884)	15	(75,107)
	Total Region M	15	2,073	15	(5,544)	15	(16,836)	15	(33,922)	15	(53,884)	15	(75,107)

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Total Regional WMS Volume – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

Unaccounted for Conservation WMS Volume – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	2,139	2,983	5,121	2,997	2,124
2016	2,685	3,058	5,743	3,747	1,996
2017	2,743	3,133	5,876	3,747	2,129
2018	2,804	3,208	6,012	4,496	1,516
2019	2,859	3,283	6,142	5,245	897
2020	2,921	3,358	6,279	6,744	(465)
2021	2,979	3,432	6,411	8,158	(1,747)
2022	3,041	3,507	6,547	9,573	(3,026)

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[12] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity

9 Region M Challenges

Listed below are challenges the RGRWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in rural Texas is very low. Traditional conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt.

By educating communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could have a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the RGRWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The RGRWPG could educate all the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something specific for which to strive. Additionally, these utilities could be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The RGRWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in similar data collection projects in the future. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in Region M are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and RGRWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the RGRWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE

offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region M, the most common suggested activities were to install AMI with a customer engagement portal component to help reduce water loss and inform customers about their water use patterns, and to continue to use periodic, strategic water rate increases to reduce consumption. Twice-per-week watering ordinances were also suggested, and rain barrels could also be useful in some areas of the region.

See Section 9 in the State Report that is part of this document for an extended discussion on these suggested activities and why they were chosen.

Statewide Municipal Water Conservation Quantification Project
Report to the Coastal Bend Regional Water Planning Area
Region N • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

Task 1: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 2: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 3: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.

Task 4: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.

Task 5: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.

Task 6: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region N make up approximately 370,000 in population by 2020, which is 60 percent of the region's total projected 2020 population.
- Participating utilities make up 72 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of two participating water utilities in place—and without further enhancement—Region N as a whole is projected to fall short of its recommended 2020 water conservation supply volume by 1,022 acre-feet per year.
- These conservation savings estimates will fall short of the region's 2022 supply volume by 253 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of two participating water utilities in place—and without further enhancement—these two utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 1,959 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2023 supply volume by 472 acre-feet per year, but will fall short of their 2024 volume by 24 acre-feet per year.
- Of those utilities surveyed, the region averages two activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region N is an 11-county area near the Gulf of Mexico. The major water demand areas are primarily municipal systems in the greater Corpus Christi area.

The Region N Plan states, "[t]he purpose of the municipal water conservation water management strategy is to evaluate the potential for additional municipal water conservation for inclusion in the Regional Water Plan to meet a part of the projected water needs (shortages) of each municipal entity." The plan calls for 17,041 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016l). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.
[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region N are 3,367 acre-feet per year for 2020, 10,046 acre-feet per year for 2030, 15,000 acre-feet per year for 2040, 15,702 acre-feet per year for 2050, and 16,485 acre-feet per year for 2060.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region N, one utility met these criteria and was contacted for participation. In order to gain valuable insight about water conservation in Region N, the City of Corpus Christi was also contact and agreed to participate. Overall, two utilities accepted and were included in the results:

Nueces County WCID #3	Corpus Christi

These utilities represent approximately 60 percent of the 2020 population of Region N and 72 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Each of the participating utilities received a report on the results of its water conservation activities and water loss efforts as part of the project. This report summarizes the savings from the individual utility reports within Region N.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a

common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Determining Supply Volumes

To develop WMS supply volumes for municipal conservation, Region N planners used a target of 140 GPCD,[3] as recommended by the Water Conservation Implementation Task Force. The objective of recommended BMPs is to reduce demand by one percent per year for WUGs over 140 GPCD (Texas Water Development Board, 2016l).

4.2 Approach to Meeting Recommended Supply Volumes

The Coastal Bend Regional Water Planning Group (CBRWPG) made the following recommendations for municipal conservation:

- Water conservation pricing
- Prohibition on wasting water

[3] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

- School education
- Landscape irrigation conservation
- Metering connections and retrofits
- Plumbing and retrofits and replacements
- Other BMPs identified by WUGs

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region N. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region N.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
N	2	1	0	0	0	0	0	1	0	0	0	4	2.0

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How can conservation activity be measured accurately to ensure Region N is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[4] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[5] for that year.[6] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[7] for water loss GPCD[8] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried

[4] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[5] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).
[6] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.
[7] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

<u>Savings Quantified by the Utility</u>

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

<u>Accelerated Plumbing Code Savings (PCS)</u>

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility’s service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Coastal Bend Regional Water Plan recommends that Region N should achieve 17,041 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the two utilities surveyed in this region are estimated to meet their portion of WMS supply volume through the year 2023. Beyond that, if no other actions are taken, the region is estimated to accrue a deficit of 6,556 acre-feet per year by 2070. Non-participating municipal WUGs have a WMS supply volume for municipal conservation of 5,259 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the two participating utilities. These utilities constitute approximately 60 percent of the region's population and account for 72 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
N	Meeting	1	1,998		0		0		0		0		0
	Not Meeting	1	(40)	2	(3,000)	2	(6,651)	2	(6,401)	2	(6,501)	2	(6,566)
	Total Region N	2	1,959	2	(3,000)	2	(6,651)	2	(6,392)	2	(6,503)	2	(6,566)

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

<u>Total Savings from All Conservation Activity for Participating Utilities</u> – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

<u>Total Regional WMS Volume</u> – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

<u>Unaccounted for Conservation WMS Volume</u> – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	859	778	1,637	1,496	140
2016	3,419	799	4,218	1,871	2,347

2067	4,046	1,156	5,202	16,874	(11,672)
2068	4,051	1,158	5,210	16,930	(11,720)
2069	4,057	1,161	5,218	16,985	(11,768)
2070	4,062	1,164	5,226	17,041	(11,815)

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[11] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[11] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity
2015	778	859											1,637
2016	799	3,419											4,218
2017	820	3,441											4,261
2018	840	3,463											4,304
2019	861	3,486											4,346
2020	881	3,508											4,389
2021	889	3,530											4,419
2022	897	3,552											4,450
2023	905	3,575											4,480
2024	913	3,597											4,510
2025	921	3,619											4,540
2026	928	3,641											4,570
2027	936	3,664											4,600
2028	944	3,686											4,630
2029	952	3,708											4,660
2030	960	3,731											4,690
2031	965	3,743											4,708
2032	970	3,756											4,725
2033	974	3,769											4,743
2034	979	3,781											4,760
2035	984	3,794											4,778
2036	989	3,806											4,795
2037	994	3,819											4,813
2038	999	3,832											4,830
2039	1,004	3,844											4,848
2040	1,008	3,857											4,866

2042	1,025	3,872											4,897
2043	1,033	3,880											4,913
2044	1,041	3,888											4,928
2045	1,049	3,895											4,944
2046	1,057	3,903											4,960
2047	1,065	3,911											4,976
2048	1,073	3,918											4,991
2049	1,081	3,926											5,007
2050	1,089	3,933											5,023
2051	1,094	3,941											5,035
2052	1,099	3,948											5,047
2053	1,104	3,956											5,060
2054	1,109	3,963											5,072
2055	1,114	3,971											5,084
2056	1,118	3,978											5,097
2057	1,123	3,986											5,109
2058	1,128	3,993											5,121
2059	1,133	4,001											5,134
2060	1,138	4,008											5,146
2061	1,140	4,014											5,154
2062	1,143	4,019											5,162
2063	1,146	4,024											5,170
2064	1,148	4,030											5,178
2065	1,151	4,035											5,186
2066	1,153	4,041											5,194
2067	1,156	4,046											5,202
2068	1,158	4,051											5,210
2069	1,161	4,057											5,218
2070	1,164	4,062											5,226

9 Region N Challenges

Listed below are challenges the CBRWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in small towns throughout Texas is very low. Traditional conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt.

By educating communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could have a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the CBRWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The CBRWPG could educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something specific for which to strive. Additionally, these utilities could be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The CBRWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in future similar data collection projects. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in the state are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and CBRWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the CBRWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region N, the most common suggested activities were to install AMI with a customer portal component to help reduce water loss and inform customers about their water use patterns, and to use periodic, strategic water rate increases to reduce consumption. Rain barrels in this part of the state can be effective, and twice-per-week watering ordinances offer significant savings that have not yet been tapped.

See Section 9 in the State Report that is part of this document for an extended discussion on these suggested activities and why they were chosen.

Statewide Municipal Water Conservation Quantification Project
Report to the Llano Estacado Regional Water Planning Group
Region O • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

> **Task 1**: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 2**: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 3**: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.
>
> **Task 4**: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.
>
> **Task 5**: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 6**: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- Participating utilities in Region O make up approximately 300,000 in population by 2020, which is 55 percent of the region's total projected 2020 population.
- Participating utilities make up 62 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of six participating water utilities in place—and without further enhancement—Region O as a whole is projected to exceed its recommended 2020 water conservation supply volume by 1,226 acre-feet per year.
- With the current conservation activities of six participating water utilities in place—and without further enhancement—these six utilities are projected to exceed their collective recommended 2020 water conservation supply volume by 2,816 acre-feet per year.[1]
- Without further activity, these utilities are projected to exceed their collective 2070 supply volume by 4,190 acre-feet per year.
- Of those utilities surveyed, the region averages 2.7 activities performed per utility

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region O is a 21-county region encompassing the Panhandle of Texas. It is a sparsely populated, agricultural region. This region is not considered a rapidly growing area of the state.

The Region O Plan states, "[i]n addition to lowering overall water demand, municipal water conservation can level out the peak demand experienced in the summer. Therefore, conservation can delay the need for new water supply projects and/or reduce the scale of new projects." The plan calls for 5,774 acre-feet of savings to come from municipal water conservation annually by 2070[2] (Texas Water Development Board, 2016m). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

---

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region O are 4,204 acre-feet per year for 2020, 4,403 acre-feet per year for 2030, 4,774 acre-feet per year for 2040, 5,071 acre-feet per year for 2050, and 5,419 acre-feet per year for 2060.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region O, nine utilities met these criteria and were contacted for participation. Six utilities accepted and were included in the results:

Brownfield	Lubbock
Lamesa	Seminole
Levelland	Silverton

These utilities represent approximately 55 percent of the 2020 population of Region O and 62 percent of the 2020 WMS supply volume for municipal water conservation for the region.

Each of the participating utilities received a report on the results of its water conservation activities and water loss efforts as part of this project. This report summarizes the savings from the individual utility reports within Region O.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Determining Supply Volumes

To develop WMS supply volumes for municipal conservation, Region O planners used a target of 140 GPCD,[3] as recommended by the Water Conservation Implementation Task Force. The plan recommends that WUGs over 140 GPCD reduce demand by 0.5 percent per year until 140 GPCD is reached (Texas Water Development Board, 2016m).

4.2 Approach to Meeting Recommended Supply Volumes

The Llano Estacado Regional Water Planning Group (LERWPG) recommended the following municipal conservation strategies (activities) for the WUGs within Region O:

- Administrative which includes outdoor water audits and public education
- Residential outdoor – identify high-use residential customers and target programs such as water audits, education on landscaping, and rebate programs
- Commercial – encourage appliance upgrades such as toilets, washing machines, and carwash upgrades.

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utilities in Region O. Further details on these

[3] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region O.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
O	6	6	1	2	0	0	0	0	0	0	1	16	2.7

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

How can conservation activity be measured accurately on a large scale to ensure Region O is meeting the marks set out in its regional water plan?

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[4] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[5] for that year.[6] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[7] for water loss GPCD[8] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

---

[4] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[5] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).
[6] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.
[7] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

<u>Savings Quantified by the Utility</u>

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

<u>Accelerated Plumbing Code Savings (PCS)</u>

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections

for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility's service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may

create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Llano Estacado Regional Water Plan recommends that Region O should achieve 5,774 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the six utilities surveyed in this region are estimated to exceed their portion (3,764 acre-feet per year) by 4,190 acre-feet per year. Non-participating municipal WUGs have a WMS supply volume for municipal conservation of 2,010 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region’s participating utilities’ quantified savings estimates are progressing toward meeting their collective 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the six participating utilities. These utilities constitute approximately 55 percent of the region’s population and account for 62 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities

currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

2070	6,405	1,546	7,952	3,764	0	3,764	4,190

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
O	Meeting	3	3,007	3	3,268	3	3,538	4	3,847	4	4,165	4	4,465
	Not Meeting	3	(191)	3	(214)	3	(225)	2	(238)	2	(257)	2	(275)
	Total Region O	6	2,816	6	3,054	6	3,313	6	3,609	6	3,908	6	4,190

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

<u>Total Savings from All Conservation Activity for Participating Utilities</u> – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

<u>Total Regional WMS Volume</u> – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

<u>Unaccounted for Conservation WMS Volume</u> – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

---

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume
2015	493	944	1,437	1,868	(432)
2016	888	950	1,838	2,336	(498)
2017	4,359	955	5,314	2,336	2,979
2018	4,392	961	5,353	2,803	2,550
2019	4,425	966	5,391	3,270	2,121
2020	4,458	972	5,430	4,204	1,226

2070	6,405	1,546	7,952	5,774	2,178

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[11] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[11] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

Table 8-1. Savings from Most Widely Used Conservation Activities (in acre-feet).

Year	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	AMI with Customer Portal	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Savings from All Conservation Activity
2015	944	433		59									1,437

2070	1,546	1,037	5,274	95									7,952

9 Region O Challenges

Listed below are challenges the LERWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in small towns throughout the Panhandle is relatively low. Traditional municipal conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt.

By educating communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could have a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the LERWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The LERWPG could educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something specific for which to strive. Additionally, these utilities could be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities as part of this project.

The LERWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They should also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in similar data collection projects in the future. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities throughout Texas are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and LERWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the LERWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region O, the most common suggested activities were to install AMI with a customer engagement portal component to help reduce water loss and inform customers about their water use patterns, and to use periodic, strategic water rate increases to reduce consumption.

Statewide Municipal Water Conservation Quantification Project
Report to the Lavaca Regional Water Planning Group
Region P • 2017

1 Executive Summary

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the 2017 State Water Plan. The project was also tasked with identifying activities that participating water utilities could pursue to meet future goals.

In fall of 2016, the TWDB contracted with Averitt & Associates, Inc., to complete the project.

The following tasks were developed under the guidance of the TWDB:

> **Task 1**: Develop an approach to estimate the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 2**: Prepare an assessment of the implementation of recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 3**: Quantitatively determine on an annual pro-rata basis the implementation of recommended municipal water conservation strategies required to meet the water conservation goals in the approved 2016 regional water plans.
>
> **Task 4**: Incorporate the use of the TWDB's Best Management Practices (BMP) Guide as appropriate.
>
> **Task 5**: Review the recommended municipal water conservation strategies in the approved 2016 regional water plans.
>
> **Task 6**: Review the TWDB's 2012 Water Conservation Savings Quantification Study (BBC Research and Consulting, 2012), and incorporate relevant findings as appropriate.

1.1 Key Findings

- The participating utility in Region P makes up approximately 12,000 in population by 2020, which is 24 percent of the region's total projected 2020 population.
- The participating utility makes up 52 percent of the region's recommended 2020 municipal conservation goal (supply volume).

- With the current conservation activities of the one participating water utility in place—and without further enhancement—Region P as a whole is projected to fall short of its recommended 2020 water conservation supply volume by 70 acre-feet per year.
- These conservation savings estimates will fall short of the region's 2070 supply volume by 517 acre-feet per year if no other conservation activities are pursued.
- With the current conservation activities of the one participating water utility in place—and without further enhancement—this utility is projected to exceed its recommended 2020 water conservation supply volume by 30 acre-feet per year.[1]
- Without further activity, this utility is projected exceed its 2025 supply volume by two acre-feet per year, but will fall short of its 2070 volume by 179 acre-feet per year.
- The participating utility employs two measurable conservation activities to achieve these results.

2 Introduction

The State Water Plan divides the state into 16 regions. Each region possesses its own environmental characteristics, demographics, and water supply concerns and develops its own water management strategies that can be used to meet the needs identified throughout the 50-year planning period.

Region P is located along the southeastern Texas coast and consists of all or part of three counties. It is the smallest and least populated planning region. El Campo is the primary population hub. Region P is not considered a rapid growth area of the state.

The Region P Plan states, "[t]he Lavaca Regional Water Planning Group (LRWPG) feels it is important to recommend municipal conservation as a water management strategy to encourage conservation in the region, and to aid municipalities in obtaining funding to perform conservation measures such as leak detection and repair, and installing smart meters." The plan calls for 674 acre-feet per year of savings to come from municipal water conservation by 2070[2] (Texas Water Development Board, 2016n). Water conservation activities and water loss mitigation efforts are combined in this region to arrive at this WMS supply volume for municipal water conservation.

---

[1] See Section 7 for details on number of individual participating utilities in each region meeting and not meeting recommended supply volumes via quantified savings estimates.

[2] This value is the recommended water management strategy supply volume for municipal water conservation. The decadal supply volumes for Region P are 209 acre-feet per year for 2020, 323 acre-feet per year for 2030, 444 acre-feet per year for 2040, 607 acre-feet per year for 2050, and 590 acre-feet per year for 2060.

3 Criteria and Participation

Utilities were targeted for participation in the study using criteria supplied by the TWDB. Utilities that have a five-year water conservation plan on file with the agency, identify municipal conservation as a WMS in their regional water plans, and have a need (shortage) within the first two decades of the planning period were invited to participate in this voluntary project.

Outreach methods included presentations to the regional water planning groups (RWPG), direct introductory emails to appropriate utility staff with an official letter from the TWDB, phone calls, personal visits, and multiple follow-ups. For most utilities, in-person interviews were conducted to complete data collection and the interview process, while over-the-phone interviews and emailed interview responses were used for some smaller utilities.

In Region P, no utilities met these criteria. In order to gain valuable insight about water conservation in Region P, the City of El Campo was contacted and agreed to participate.

This utility represents approximately 24 percent of the 2020 population of Region P and 52 percent of the 2020 WMS supply volume for municipal water conservation for the region.

El Campo received a report on the results of its water conservation activities and water loss efforts and is included as a part of this report. This report summarizes the savings from the individual utility report within Region P.

4 Regional Planning Group Approach to Municipal Water Conservation

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing

- Steam electric power generation

What is a recommended water management strategy?

A recommended WMS is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

4.1 Approach to Determining Supply Volumes

To develop WMS supply volumes for municipal conservation, Region P planners used a target of 140 GPCD,[3] as recommended by the Water Conservation Implementation Task Force. The objective of recommended activities is to reduce demand by five percent per decade for WUGs over 140 GPCD (Texas Water Development Board, 2016n).

4.2 Approach to Meeting Recommended Supply Volumes

Although the Lavaca Regional Water Planning Group (LRWPG) does not specifically recommend any particular municipal water conservation strategies, the following were mentioned:

- Drought tolerant landscape
- Smart water meters
- Public education and outreach
- Rebate and incentive programs
- Local ordinances that increase efficiency

[3] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

- Increased water utility efficiency
- Conservation rate structures

For comparison, Table 4-1 illustrates which measurable municipal conservation activities are being implemented by the participating utility in Region P. Further details on these categories of activities, which were the most prevalently implemented throughout the state can be found in Section 8 of this regional report.

Table 4-1. Actual Implemented Activities of Participating Utilities (since 2011) in Region P.

Region	Water Loss Reduction	Water Rate Increases	2x Watering Ordinance	Conservation Pricing	Utility Outdoor Irrigation Audits	Vendor Take-home Device Kits	Vendor Retrofit Program	Rainwater Barrels	Vendor Outdoor Irrigation Audits	Accelerated PCS	Other	Total Activities	Average Per Utility
P	1	1	0	0	0	0	0	0	0	0	0	2	2.0

5 Project Approach

The following question was used as the basis for developing an approach to complete each region's project:

> *How can conservation activity be measured accurately to ensure Region P is meeting the marks set out in its regional water plan?*

A 2012 BBC Research water conservation savings quantification study prepared for the TWDB identified the two primary ways that water providers measure water conservation—top-down and bottom-up.

Using the study's terminology, "[t]op-down refers to estimation approaches based on aggregate water use changes; bottom-up refers to quantification based on adding up savings estimates for individual conservation measures," (BBC Research and Consulting, 2012).

A common top-down approach used by many states—and indeed accomplished by the TWDB via its water conservation annual reports—is to compare gallons per capita per day (GPCD) consumption from year to year, or to compare current year levels with a five-year rolling average.

However, per capita use from utility to utility can vary greatly. A variety of factors may influence GPCD consumption, including climate, population, utility education efforts, building density, customer class makeup, and regional economic conditions. In addition, based on data gathered during the project, it was evident that GPCD values are often misreported and that discrepancies still exist regarding how they are calculated and which baselines to establish.

Quantifying conservation activities using a bottom-up method can help isolate reliable, measurable savings from the sometimes-volatile swings in GPCD levels across utilities.

For regional planners, this is an important advantage to the bottom-up approach. If water conservation savings from quantifiable activities are conservatively estimated and better represent the supply volumes genuinely resulting from conservation efforts, then planning supply volumes from other water management strategies becomes a more realistic endeavor. It essentially helps planning efforts match more closely with the realities on the ground.

The BBC Research study concluded that "…utilities must have estimates of reliable water savings…thus, there is a need for greater focus and standardization in procedures for estimating water savings itself." And, finally, that, "[t]he combination of top-down approaches to evaluate overall usage with bottom-up approaches for program evaluation is likely the best method for comprehensive analysis of conservation savings…" (BBC Research and Consulting, 2012).

Thus, the approach for this project was to establish a uniform, standard method of quantifying savings for all participating utilities, while noting and comparing the water use increase or decrease represented by changes in GPCD consumption levels in their individual utility reports.

6 Methodology

6.1 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[4] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD[5] for that year.[6] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

6.1.1 Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[7] for water loss GPCD[8] and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the process because water loss will inevitably increase or decrease in later years.

---

[4] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[5] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

[6] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[7] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach utilized here was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

6.2 Quantifiable Savings

The key to a project of this type being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

6.2.1 Caveats to specific activity savings

Several activities were encountered but could not be accurately quantified because of unreliable or incomplete savings estimates. For example, neither athletic field, park, nor golf course conservation efforts were included because there was too much variability from utility to utility to be consistent and accurate.

For a few activities, certain assumptions were also made that deserve further explanation because the activities contribute to considerable savings over time.

<u>Water Rate Increases</u>

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, the savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were also made for water rate increases:

- The study assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity study estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Savings Quantified by the Utility

For some large, sophisticated utilities, such as City of Austin, Dallas Water Utilities, and San Antonio Water System, quantified savings estimates were used as the projections. These utilities have multiple staff members dedicated to water conservation and had specific, reliable savings estimates for all of their efforts. Findings showed that uniform savings estimates used throughout the process for other utilities tracked closely with their internal savings figures.

Accelerated Plumbing Code Savings (PCS)

The regional and state water plans have accounted for passive savings that will occur due to the natural replacement of inefficient water fixtures and appliances pursuant to federal and state plumbing code requirements. Some regional water plans expect all passive PCS will be achieved by 2045. By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS. These values should be helpful when planners are assessing future supply volumes that can be expected from these activities.

Activity savings falling under this category were carried forward through 2070 because, due to plumbing code and efficiency standards, these high efficiency fixtures and devices will be replaced by another equally as efficient item. The project considered curbing savings by 2045, but to be consistent with other persistent savings, such as the projections for water rate increases and permanent ordinances, savings were carried through to the end of the planning period. It is also likely that plumbing code and efficiency standards will undergo further revision during this time, which may affect this timeline.

6.2.2 Interactions among conservation activity savings

The 2012 TWDB quantification study identified three types of interaction effects: competitive, independent, and synergistic (BBC and Research, 2012).

> "[Competitive] results in water savings less than the sum of water savings from each measure when implemented alone. For example, a rebate program for installation of water-efficient irrigation systems may be expected to save a certain volume of water. When coupled with passage of outdoor water restrictions, however, savings from the efficient systems may be lower than they would otherwise be (e.g., watering occurs once per week rather than twice, thus overall savings are reduced). [Independent] indicates their savings are strictly additive, such as water use efficiency from a cooling tower retrofit and installation of waterless urinals in a commercial facility. [Synergistic] occurs when two measures result in a combined savings that is greater than the sum of savings if the measures were implemented individually, such as might occur with installation of drought-tolerant plant materials and education on irrigation techniques."

This study primarily encountered competitive savings interactions with outdoor watering measures. With ordinances restricting outdoor watering, there were occasionally other measures in place to enhance or further curb outdoor watering that were not factored into the estimates, such as irrigation controller rebates, stricter ordinance enforcement, and outdoor lawn audits.

6.2.3 Limitations to data collection and the interview process

The projections in this report indicate the best information available, as provided by utility staff. Several times staff-provided data did not match records on file with the TWDB or did not match another staff member's work from previous records.

It is also possible that the report does not account for all ongoing activities. Some activities within a utility’s service area are implemented on a micro-scale that is unquantifiable to date. Individual households and businesses may be implementing unknown, and therefore unquantifiable, conservation measures.

Lastly, staff turnover or delegation over certain data sometimes limited the collection of full interview responses.

6.3 Discrepancies with Regional Water Plan

For individual reports, a utility's service area population was used if there was any difference with WUG population in the regional water plan. When assessing the extent of water conservation activities being implemented by a utility, the following factors may create a discrepancy between this report and the regional or state water plan:

This study focused on the conservation activities employed by utilities within their entire service area. In some cases, service area population and WUG population were the same, but in many cases they were different. Utilities implement conservation activities to the entire area they serve, not just within political boundaries. Therefore, it was logical to track conservation activities based on how many people were affected and to whom the activities were targeted.

Regional splits for population and WMS supply volumes were not used in this report. If a utility is offering service in two different water planning regions, the utility was assigned to the region in which it principally lies. If WMS supply volumes were split between two water planning regions, those volumes were combined and the utilities conservation savings were compared to the total volume. The project's purpose was to assess where the utilities stand in meeting their conservation goals and how can they improve their results. There is little benefit to the utility to know how much conservation is being applied to which region or for the utility to focus on meeting the supply volumes according to the boundaries of different regions.

As a result, the percentage of participating utilities' WMS supply volumes compared to the regional total for WMS supply volumes may be affected by the fact that the water plans adhere to population and WMS supply volumes splits along regional boundaries.

7 Where Does the Region Stand in Meeting Its Municipal Conservation Supply Volumes?

The 2016 Region P Water Plan recommends that Region P should achieve 674 acre-feet per year of savings to meet the 2070 WMS supply volume for municipal water conservation. The results of this study indicate that the utility surveyed in this region is estimated to meet the recommended supply volume for municipal conservation through the year 2025. If no other actions are taken, El Campo is estimated to accrue a deficit of 179 acre-feet per year by 2070. The non-participating municipal WUGs have a WMS supply volume for municipal conservation of 338 acre-feet per year by the end of the planning period.

Table 7-1 shows how the region's participating utility's quantified savings estimates are progressing toward meeting its 2070 future supply volumes for municipal water conservation. The table contains the sum of the supply volumes for the one participating utility. These utilities constitute approximately 24 percent of the region's population and account for 52 percent of this water management strategy.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed in individual reports under the itemized activity. The following definitions pair with the column headers in Table 7-1.

Conservation Activity Savings for Participating Utilities – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

Water Loss Reduction Savings (as of 2015) for Participating Utilities – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[9] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

Total Savings from All Conservation Activity for Participating Utilities – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

Conservation WMS Volume for Participating Utilities – The sum of the recommended municipal water conservation supply volumes in the regional plan for decades ranging from 2020 to 2070 for participating utilities.

Water Loss Reduction WMS Volume for Participating Utilities – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If any of the participating WUGs has a separate WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume for Participating Utilities – The sum of Conservation WMS Volume for Participating Utilities and Water Loss Reduction WMS Volume for Participating Utilities.

Over (Short) – The volume that the participating utilities' total quantified savings estimates for all current conservation activities (since 2011), including water loss reduction, are over or below the recommended total WMS supply volume for municipal water conservation in the regional water plan for those utilities. If the amount falls below the WMS volume, it will appear in parentheses.

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Table 7-1. Participating Utilities' Total Estimated Savings Compared to Participants' Conservation WMS Supply Volumes (in acre-feet per year).

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Conservation WMS Volume for Participating Utilities	Water Loss Reduction WMS Volume for Participating Utilities	Total Yearly WMS Volume for Participating Utilities	Over (Short)

Table 7-2 lists the number of utilities in the region meeting and not meeting their respective WMS supply volumes via quantified savings assessed in the project. The table shows this comparison for each decade in the planning period from 2020 through 2070, and illustrates how individual participating utilities are progressing toward meeting recommended supply volumes, rather than the region as a whole. As there is only one partipipating utility in this region, the table shows El Campo's decadal results. El Campo is exceeding its 2020 recommended volume by 30 acre-feet per year and falling short through the rest of the planning period.

Table 7-2. Participating Utilities Estimated to be Meeting Respective WMS Supply Volumes.

Region		Number of Utilities	2020 Regional Supply Volumes: Over (Short)	Number of Utilities	2030 Regional Supply Volumes: Over (Short)	Number of Utilities	2040 Regional Supply Volumes: Over (Short)	Number of Utilities	2050 Regional Supply Volumes: Over (Short)	Number of Utilities	2060 Regional Supply Volumes: Over (Short)	Number of Utilities	2070 Regional Supply Volumes: Over (Short)
P	Meeting	1	30		0		0		0		0		0
	Not Meeting		0	1	(27)	1	(91)	1	(183)	1	(176)	1	(179)
	Total Region P	1	30	1	(27)	1	(91)	1	(183)	1	(176)	1	(179)

Table 7-3 shows how the region's participating utilities' quantified savings estimates are progressing toward meeting the entire region's 2070 recommended supply volumes for municipal water conservation. The following definitions pair with the column headers in Table 7-3.

<u>Conservation Activity Savings for Participating Utilities</u> – All quantified activities currently being performed by participating utilities, excluding savings from water loss reduction. The summary of these savings can be referenced in Table 8-1.

<u>Water Loss Reduction Savings (as of 2015) for Participating Utilities</u> – The volume the participating utilities are realizing from water loss reduction. For individual utilities, savings is determined by taking the difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB.

<u>Total Savings from All Conservation Activity for Participating Utilities</u> – The sum of Conservation Activity Savings for Participating Utilities and Water Loss Reduction Savings (as of 2015) for Participating Utilities.

<u>Total Regional WMS Volume</u> – The sum of annual WMS supply volumes for municipal water conservation and water loss reduction for the entire region.

<u>Unaccounted for Conservation WMS Volume</u> – The amount that the participating utilities' total quantified savings for all current conservation activities (since 2011), including water loss reduction, is estimated to be over or below the recommended Total Regional WMS Volume. If quantified savings estimates fall below the WMS volume, it will appear in parentheses. This volume is considered unaccounted for because it includes

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

the WMS supply volumes for all non-participating municipal WUGs in the region for which savings have not been quantified, as well the volumes for participating utilities that exceed quantified savings estimates.

Table 7-3. Comparison of Quantified Savings of Participating Utilities and Municipal Conservation WMS Supply Volumes for Entire Region.

Year	Conservation Activity Savings for Participating Utilities	Water Loss Reduction Savings (as of 2015) for Participating Utilities	Total Savings from All Conservation Activity for Participating Utilities	Total Regional Yearly WMS Volume	Unaccounted for Conservation WMS Volume

8 Activity Findings

Table 8-1 shows the most prevalently implemented conservation activities in the state. The values in the table show how much these activities are saving specifically in this region.

For specific formulas used to quantify these activities, refer to Section 6 in the State Report as part of this document.

Terms used in Table 8-1:

Water Loss Reduction – The amount of water savings (or loss)[11] due to efforts that reduce leaks and breaks, customer meter inaccuracy, data discrepancies, and other unaccounted-for water.

Water Rate Increases – Strategic increases to a utility's water service rates that result in reduced consumption.

2x Watering Ordinance – An ordinance that permanently restricts outdoor watering schedules to two times per week or less, year-round. Savings are assumed to increase at the same pace as increasing demand over time.

Conservation Pricing – The use of rate structures that discourage the inefficient use or waste of water.

AMI with Customer Portal – These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

Utility Outdoor Irrigation Audits – Audits performed on single-family residences by licensed irrigators that work in-house at the utility. These audits reduce water by surveying current outdoor water use, making recommendations, and occasionally installing or repairing equipment to further curb use. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Vendor Take-home Device Kits – Kits distributed by a third-party vendor to students that include water conserving devices, including showerheads, kitchen and bathroom aerators,

[11] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will be negative because more water is being lost than the baseline amount.

toilet flappers, and leak detectors. Savings for the showerhead in these kits were counted separately from savings in the accelerated PCS category. Each item in the kit is conservatively assumed to have a five-year useful life and an adoption rate of 15 percent for all kits distributed (Frontier Associates, 2015).

Vendor Retrofit Program – Third-party vendor that carries out a program targeting multi-family residential, hotel, and commercial customers. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets, and replacing sink aerators. This program operates outside of the utility's top-down planned efforts and is achieving notable savings, so it was deemed necessary to account for its results. Savings from the toilet-rebuilding portion of the program were counted separately from savings in the accelerated PCS category.

Rainwater Barrels – Barrels and other rainwater collection systems that store rain for later use and replace potable water. A 10-year useful life is assumed for most barrels (GDS Associates, 2002).

Vendor Outdoor Irrigation Audits – Third-party contractor that performs audits on single-family residences similar to those conducted by in-house utility staff. Savings for this activity are assumed to have a 20 percent annual decay rate as consumer behavior and the effectiveness of other audit features lessen over time (A&N Technical Services, 2005).

Accelerated PCS – By offering rebates or other incentives, directly replacing fixtures, or by giving away various items, utilities can accelerate anticipated passive PCS.

Other – Savings from any conservation activities not included in the other categories. All specific savings from these activities are quantified in detail in individual utility reports.

9 Region P Challenges

Listed below are challenges the LRWPG and its associated utilities are facing regarding implementing water conservation as a WMS, as identified by this study.

9.1 Regional Communication

- From interview responses, it was made clear that most utilities are largely unaware of impending regional shortages or any recommendations made by the regional water planning group to specifically address municipal conservation.
- Utilities often do not know what their role is regarding regional conservation supply volumes.

9.2 Teamwork and Accomplishment

Residential consumption in small towns throughout Texas is very low. Traditional conservation activities, therefore, are not seen as particularly necessary. It was evident through interviews in less populated towns that the amount of savings that are possible from municipal conservation efforts seems insignificant in relation to the amount of water being used by other sectors, such as agriculture and larger cities, and therefore harder to adopt.

By educating communities on their portion of the regional WMS supply volume for municipal water conservation objectives, they could have a sense of doing their part by achieving reasonable results.

10 Recommendations

Listed below are recommendations for the LRWPG and utilities.

10.1 Participation and Communication

- Utilities should fully participate in the regional water planning process to become knowledgeable about the planning process and provide stakeholder input.
- The LRWPG could educate the utilities in the area about their specific WMS supply volume for municipal water conservation objectives. This gives them something very specific for which to strive. Additionally, these utilities could be informed on what options and activities are available to them and what they can expect to achieve by implementing them. Each participating utility was issued a report that gave general recommendations about how to move forward with municipal conservation activities.

The LRWPG could sponsor stakeholder meetings to keep the issue relevant for these utilities. They could also establish a reliable, efficient communication structure that connects regional planners to all utilities to periodically discuss progress.

10.2 Continue Data Collection

Encourage broader participation in similar data collection projects in the future. Increased participation will be imperative in future years to ensure accuracy, foster a more complete understanding of regional conservation, and achieving regional supply volumes. Continued data collection will make the WMS for municipal conservation an attainable ongoing strategy for the planners. Keeping up with progress will be essential to further development of the strategy. If you can measure it, you can manage it.

10.3 Training and Financing Opportunities

Many utilities in Texas are considering AMI. AMI is a popular and growing activity throughout the state. It represents a new way of informing consumers about their consumption patterns and is a powerful tool to change behavior. Most small utilities do not have the expertise to pursue this option. The TWDB and LRWPG could help those communities take advantage of new technology. Meters must be replaced over time, and AMI could help many municipalities reduce staff overhead along with its water-savings benefits. Perhaps the LRWPG and the TWDB could continue to sponsor training seminars, which should include training on how to access State Water Implementation Fund for Texas (SWIFT) and other TWDB funding programs.

Water planners, managers, and private sector businesses should be educated on the opportunities that Property Assessed Clean Energy (PACE) brings to the water conservation efforts of larger businesses. Many utilities can benefit from their large industrial and commercial customers being more efficient with their water usage. PACE offers a unique way to finance such projects so that they become attractive options. A PACE-financed water conservation project also improves cash flow for the business and saves water.

In order for a private entity to participate in PACE, either the city or county must pass a resolution to participate in the program. Once this is done, the entity has the option to "self-assess" a lien on their property that will allow them to finance a water or energy-saving project over enough time to guarantee a positive cash flow.

10.4 Adopting Activities

Utilities should consider adopting the advanced municipal conservation activities detailed in their individual reports.

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

A detailed cost-benefit analysis on these activities could be performed based upon utility size. The use of specific water purchase and other cost data would also allow for the calculation of savings and cost estimates for these utilities.

For Region P, the suggested activity was to install AMI with a customer portal component to help reduce water loss and inform customers about their water use patterns.

Appendix E - Individual Reports by Region

Region A Individual Reports

Statewide Water Conservation Quantification Project
City of Amarillo Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used By Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2015b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

> after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Amarillo's current water conservation activities and their quantified savings to two metrics: 1) Region A Water Plan's (Texas Water Development Board, 2016) recommended WMS supply volumes for municipal conservation, and 2) Amarillo's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.

The 5- and 10-year goals in Amarillo's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[5] are expressed in decreasing total GPCD[6] consumption and water loss GPCD.[7] [8]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households

[5] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.
[6] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365
[7] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.
[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. This value is the difference between each individual utility's baseline[9] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Amarillo with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [11] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[11] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	0	512	512	251	0	251	261
2016	93	518	611	314	0	314	297
2017	94	524	617	314	0	314	304

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Amarillo's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[12] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	227	0	0	0
1	2015	200,502	217	761	512	(249)
2	2016	202,720	206	1,539	611	(928)
3	2017	204,938	196	2,334	617	(1,716)
4	2018	207,155	185	3,145	624	(2,522)
5-year Goal	2019	209,373	175	3,974	630	(3,343)
6	2020	211,591	174	4,093	637	(3,456)
7	2021	214,013	173	4,218	644	(3,574)
8	2022	216,434	172	4,345	651	(3,694)
9	2023	218,856	171	4,473	658	(3,815)
10-year Goal	2024	221,277	170	4,604	665	(3,939)

[12] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Amarillo's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-3.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[13] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	15.00	0	0	0
1	2015	200,502	15.00	0	512	512
2	2016	202,720	15.00	0	518	518
3	2017	204,938	15.00	0	524	524
4	2018	207,155	15.00	0	529	529
5-year Goal	2019	209,373	15.00	0	535	535
6	2020	211,591	14.40	46	541	494
7	2021	214,013	13.80	94	547	453
8	2022	216,434	13.20	142	553	411
9	2023	218,856	12.60	192	559	367
10-year Goal	2024	221,277	12.00	242	565	323

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[14]
    a. Savings of 512 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[15] water loss GPCD submitted in its most recent five-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increase**
    a. Last rate increase:[16]
        i. 3% increase in 2016
    b. Estimated customer demand reduction of 0.6%
    c. Savings is cumulative and based on more than one source[17] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Rain Barrels**
    a. In Region A, estimated savings of 12.1 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
    b. Estimated 10-year useful life for most barrels

6. **Save Water Co. Commercial, Multi-family and Hotel Programs**[18]

---

[14] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[15] In the absence of having a baseline figure provided in the utility's most recently submitted five-year water conservation plan, the historic five-year average for water loss GPCD in the plan was used.
[16] Correspondence with utility staff.
[17] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.
[18] Savings figures and units serviced based on personal email communication with Kurt Goedrich, December 1, 2016.

a. Project initiated in service area in March 2016
b. Save Water completed work on 120 multi-family units in 2016.
c. Average monthly savings of 235,668 gallons
d. Annualized savings of 2.83 MG for the life of the retrofitted fixtures
e. This study estimates a lifespan of 25 years for high-efficiency toilet replacements, five years for kitchen aerators and similar devices.
f. Save Water Co. performs monthly meter readings before and after installation to quantify savings.
g. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets and replacing sink aerators.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Water Rate Increases	Rain Barrels	Save Water Co. Program	TOTAL SAVINGS
2016	90	0.21	3	93.0
2017	91	0.21	3	93.8
2018	92	0.21	3	94.7
2019	92	0.21	3	95.5
2020	93	0.21	3	96.4
2021	94	0.21	3	97.2
2022	95	0.21	3	98.1
2023	96	0.21	3	98.9
2024	97	0.21	3	99.8
2025	98	0.21	3	100.7
2026	98		3	101.3
2027	99		3	102.2
2028	100		3	103.0
2029	101		3	103.9
2030	102		3	104.7
2031	103		3	105.6
2032	104		3	106.6
2033	105		3	107.5
2034	106		3	108.4
2035	106		3	109.3
2036	107		3	110.2
2037	108		3	111.2
2038	109		3	112.1
2039	110		3	113.0
2040	111		3	113.9
2041	112		3	114.9
2042	113		3	115.9
2043	114		3	116.9
2044	115		3	117.9
2045	116		3	118.9
2046	117		3	119.8
2047	118		3	120.8
2048	119		3	121.8
2049	120		3	122.8
2050	121		3	123.8
2051	122		3	124.9
2052	123		3	126.0
2053	124		3	127.2
2054	125		3	128.3
2055	127		3	129.4
2056	128		3	130.6
2057	129		3	131.7
2058	130		3	132.8
2059	131		3	133.9
2060	132		3	135.1
2061	133		3	136.3

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
  - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
    a. Potentially 8.63% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
    b. Savings could be 1,293 MG per year with current demand.
    c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	93	518	611	1,293	314	0	314	1,590
2017	94	524	617	1,305	314	0	314	1,609
2018	95	529	624	1,318	377	0	377	1,565
2019	96	535	630	1,330	439	0	439	1,521
2020	96	541	637	1,342	565	0	565	1,414
2021	97	547	644	1,355	572	0	572	1,427
2022	98	553	651	1,367	578	0	578	1,440
2023	99	559	658	1,379	585	0	585	1,453
2024	100	565	665	1,392	591	0	591	1,465
2025	101	572	672	1,404	598	0	598	1,478
2026	101	578	679	1,416	605	0	605	1,491
2027	102	584	686	1,429	611	0	611	1,504
2028	103	590	693	1,441	618	0	618	1,516
2029	104	596	700	1,453	624	0	624	1,529
2030	105	602	707	1,466	631	0	631	1,542
2031	106	609	715	1,479	637	0	637	1,556
2032	107	615	722	1,492	643	0	643	1,571
2033	107	622	729	1,505	649	0	649	1,585
2034	108	628	736	1,518	655	0	655	1,599
2035	109	634	744	1,532	662	0	662	1,614
2036	110	641	751	1,545	668	0	668	1,628
2037	111	647	758	1,558	674	0	674	1,643
2038	112	654	766	1,571	680	0	680	1,657
2039	113	660	773	1,585	686	0	686	1,672
2040	114	666	780	1,598	692	0	692	1,686

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications
b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
c. Estimate assumes customers will save 10% of total annual use due to the portal
    i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    i. This was the most common percentage of residential use among participating utilities in this project.
    ii. Actual customer class demand percentages will vary by utility.
e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
f. Savings are assumed to increase along with demand as connections increase each year[19]
g. See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	93	518	611	201	314	0	314	498
2017	94	524	617	203	314	0	314	506

2040	114	666	780	248	692	0	692	336

Statewide Water Conservation Quantification Project
City of Borger Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2015j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Borger's current water conservation activities and their quantified savings to two metrics: 1) Region A Water Plan's (Texas Water Development Board, 2016) recommended WMS supply volumes for municipal conservation, and 2) Borger's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.

The 5- and 10-year goals in Borger's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[5] are expressed in decreasing total GPCD[6] consumption and water loss GPCD.[7] [8]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility’s service area are implemented on a micro-scale that may not be quantified. Individual households

[5] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[6] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[7] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[9] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Borger with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

This table compares all quantified conservation activity starting in 2015 and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

the study quantifies utility savings starting in 2012 for this comparison.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. The summary of these savings can be referenced in Table 5-1.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).[11]

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If the utility's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.
[11] If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Borger's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[12] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	589	0	0	0
1	2015	13,251	624	(171)	34	205
2	2016	13,348	660	(345)	34	379
3	2017	13,444	695	(521)	34	555
4	2018	13,541	731	(700)	35	734
5-year Goal	2019	13,637	766	(881)	35	916
6	2020	13,734	763	(871)	35	906
7	2021	13,783	760	(858)	35	893
8	2022	13,832	756	(845)	35	881
9	2023	13,882	753	(832)	35	867
10-year Goal	2024	13,931	750	(819)	36	854

[12] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for total GPCD from the utility's most recently submitted 5-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Borger's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[13] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-1 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	25.00	0	0	0
1	2015	13,251	26.40	(7)	34	41
2	2016	13,348	27.80	(14)	34	48
3	2017	13,444	29.20	(21)	34	55
4	2018	13,541	30.60	(28)	35	62
5-year Goal	2019	13,637	32.00	(35)	35	70
6	2020	13,734	30.60	(28)	35	63
7	2021	13,783	29.20	(21)	35	56
8	2022	13,832	27.80	(14)	35	49
9	2023	13,882	26.40	(7)	35	43
10-year Goal	2024	13,931	25.00	0	36	36

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[14]
    a. Savings of 34 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[15] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

[14] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[15] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.

5 Summary of Savings

Table 5-1. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	25.00	0
2015	13,251	18.00	34
2016	13,348	18.00	34
2017	13,444	18.00	34
2018	13,541	18.00	35
2019	13,637	18.00	35
2020	13,734	18.00	35
2021	13,783	18.00	35
2022	13,832	18.00	35
2023	13,882	18.00	35
2024	13,931	18.00	36

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs

    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs
    - Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications

b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)

c. Estimate assumes customers will save 10% of total annual use due to the portal

    i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)

d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB

    i. This was the most common percentage of residential use among participating utilities in this project.
    ii. Actual customer class demand percentages will vary by utility.

e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand

f. Savings are assumed to increase along with demand as connections increase each year[16]

g. See Table 6-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

2040	0	37	37	14	35	0	35	16

[16] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

2. Water Rate Increase
    a. For every 10% increase, estimated savings could be 2% of utility total demand.
    b. Approximately 21 MG of savings per year with current demand
    c. Savings is cumulative and based on more than one source[17] (U.S. EPA, 1998; Whitcomb, 1999)
    d. See Table 6-2 for potential savings from this measure compared with the utility's conservation goals.

Table 6-2. Current Savings + Potential Savings from 10% Water Rate Increase (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Water Rate Increase	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

[17] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

Statewide Water Conservation Quantification Project
City of Dalhart Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Dalhart's current water conservation activities and their quantified savings to two metrics: 1) Region A Water Plan's (Texas Water Development Board, 2016) recommended WMS supply volumes for municipal conservation, and 2) Dalhart's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Dalhart's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.
[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365
[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.
[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Dalhart with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

This table compares all quantified conservation activity starting in 2015 and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).[12] Refer to Tables 5-1 and 5-2 for details on these savings.

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If the utility's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	0	(134)	(134)	11	0	11	(146)
2016	6.7	(136)	(129)	14	0	14	(143)
2017	6.8	(137)	(130)	14	0	14	(145)

2046	8.5	(177)	(168)	32	0	32	(200)
2047	8.5	(178)	(170)	32	0	32	(202)
2048	8.6	(179)	(171)	32	0	32	(203)
2049	8.6	(181)	(172)	32	0	32	(204)
2050	8.7	(182)	(173)	33	0	33	(206)
2051	8.8	(183)	(175)	33	0	33	(207)
2052	8.8	(185)	(176)	33	0	33	(209)
2053	8.9	(186)	(177)	33	0	33	(210)
2054	8.9	(187)	(178)	34	0	34	(212)
2055	9.0	(188)	(179)	34	0	34	(213)
2056	9.0	(190)	(181)	34	0	34	(215)
2057	9.1	(191)	(182)	34	0	34	(216)
2058	9.2	(192)	(183)	34	0	34	(217)
2059	9.2	(193)	(184)	35	0	35	(219)
2060	9.3	(195)	(185)	35	0	35	(220)
2061	9.3	(196)	(187)	35	0	35	(222)
2062	9.4	(197)	(188)	35	0	35	(223)
2063	9.4	(198)	(189)	35	0	35	(224)
2064	9.5	(200)	(190)	36	0	36	(226)
2065	9.6	(201)	(191)	36	0	36	(227)
2066	9.6	(202)	(192)	36	0	36	(228)
2067	9.7	(203)	(194)	36	0	36	(230)
2068	9.7	(204)	(195)	36	0	36	(231)
2069	9.8	(206)	(196)	37	0	37	(232)
2070	9.9	(207)	(197)	37	0	37	(234)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Canyon's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	202	0	0	0
1	2015	8,370	194	26	(134)	(160)
2	2016	8,456	185	52	(129)	(181)
3	2017	8,543	177	79	(130)	(209)
4	2018	8,629	168	106	(132)	(238)
5-year Goal	2019	8,716	160	134	(133)	(267)
6	2020	8,802	156	148	(134)	(282)
7	2021	8,888	152	162	(136)	(298)
8	2022	8,974	148	177	(137)	(314)
9	2023	9,061	144	192	(138)	(330)
10-year Goal	2024	9,147	140	207	(140)	(347)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for total GPCD from the utility's most recently submitted 5-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Dalhart's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
Baseline	-	16.00	0	0	0
2015	8,370	14.80	4	(134)	(138)
2016	8,456	13.60	7	(136)	(143)
2017	8,543	12.40	11	(137)	(148)
2018	8,629	11.20	15	(139)	(154)
2019	8,716	10.00	19	(140)	(159)
2020	8,802	9.00	22	(141)	(164)
2021	8,888	8.00	26	(143)	(169)
2022	8,974	7.00	29	(144)	(174)
2023	9,061	6.00	33	(146)	(179)
2024	9,147	5.00	37	(147)	(184)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Loss of 134 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increase**
    a. Last rate increase:[17]
        i. 9% increase in 2016
    b. Estimated customer demand reduction of 1.8%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Water Rate Increases	TOTAL SAVINGS
2016	6.7	6.7
2017	6.8	6.8
2018	6.8	6.8
2019	6.9	6.9
2020	7.0	7.0
2021	7.0	7.0
2022	7.1	7.1
2023	7.1	7.1
2024	7.2	7.2
2025	7.2	7.2
2026	7.3	7.3
2027	7.4	7.4
2028	7.4	7.4
2029	7.5	7.5
2030	7.5	7.5
2031	7.6	7.6
2032	7.6	7.6
2033	7.7	7.7
2034	7.8	7.8
2035	7.8	7.8
2036	7.9	7.9
2037	7.9	7.9
2038	8.0	8.0
2039	8.1	8.1

2070	9.9	9.9

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	16	0
2015	8,370	60	(134)
2016	8,456	60	(136)
2017	8,543	60	(137)
2018	8,629	60	(139)
2019	8,716	60	(140)
2020	8,802	60	(141)
2021	8,888	60	(143)
2022	8,974	60	(144)
2023	9,061	60	(146)
2024	9,147	60	(147)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications

b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)

c. Estimate assumes customers will save 10% of total annual use due to the portal

   i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)

d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB

   i. This was the most common percentage of residential use among participating utilities in this project.

   ii. Actual customer class demand percentages will vary by utility.

e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand

f. Savings are assumed to increase along with demand as connections increase each year[19]

---

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

g. See Table 6-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	7	(136)	(129)	11	14	0	14	(132)
2017	7	(137)	(130)	11	14	0	14	(133)
2018	7	(139)	(132)	11	17	0	17	(137)
2019	7	(140)	(133)	12	20	0	20	(142)
2020	7	(141)	(134)	12	26	0	26	(148)
2021	7	(143)	(136)	12	26	0	26	(150)
2022	7	(144)	(137)	12	26	0	26	(151)
2023	7	(146)	(138)	12	26	0	26	(153)
2024	7	(147)	(140)	12	27	0	27	(154)
2025	7	(148)	(141)	12	27	0	27	(156)
2026	7	(150)	(142)	12	27	0	27	(157)
2027	7	(151)	(144)	12	27	0	27	(159)
2028	7	(152)	(145)	12	28	0	28	(160)
2029	7	(154)	(146)	13	28	0	28	(162)
2030	8	(155)	(148)	13	28	0	28	(163)
2031	8	(157)	(149)	13	28	0	28	(165)
2032	8	(158)	(150)	13	28	0	28	(166)
2033	8	(159)	(152)	13	29	0	29	(167)
2034	8	(161)	(153)	13	29	0	29	(169)
2035	8	(162)	(154)	13	29	0	29	(170)
2036	8	(163)	(156)	13	29	0	29	(172)
2037	8	(165)	(157)	13	30	0	30	(173)
2038	8	(166)	(158)	13	30	0	30	(175)
2039	8	(167)	(159)	13	30	0	30	(176)
2040	8	(169)	(161)	14	30	0	30	(177)

Statewide Water Conservation Quantification Project

City of Canyon Report • 2017

Deleted: TWDB

1 Introduction

Formatted: Font:12 pt

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

Deleted: to be

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

Formatted: Font:12 pt

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Formatted: Font:12 pt

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

Deleted: 5

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

Formatted: Font:12 pt

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Deleted: we

Deleted: d

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Deleted: We

Deleted: then quantified

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Deleted: Individual reports distributed to each participating utility detail these attributes.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

Formatted: Font:12 pt

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

Formatted: Font:12 pt

This report compares Canyon's current water conservation activities and their quantified savings to two metrics: 1) Region A Water Plan's (Texas Water Development Board, 2016) recommended WMS supply volumes for municipal conservation, and 2) Canyon's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Canyon's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

Deleted: we

Deleted: have

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Canyon with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

This table compares all quantified conservation activity starting in 2015 and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Deleted: Because t

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).[12] Refer to Tables 5-1 and 5-2 for details on these savings.

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If the utility's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

3.2 Utility Water Conservation Plan Goals – Total GPCD

Formatted: Font:12 pt

Table 3-2 shows how Canyon's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Deleted: 5-

Deleted: and

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Deleted: 5-

Deleted: 5

Deleted: 5

Deleted: 5

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	178	0	0	0
1	2015	14,200	176	8	87	79
2	2016	14,321	175	17	100	83
3	2017	14,441	173	25	110	84
4	2018	14,562	172	34	111	77
5-year Goal	2019	14,682	170	43	112	69
6	2020	14,803	169	49	112	64
7	2021	14,978	168	55	114	59
8	2022	15,153	167	61	115	54
9	2023	15,328	166	67	116	49
10-year Goal	2024	15,503	165	74	118	44

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for total GPCD from the utility's most recently submitted 5-year water conservation plan was used.

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Formatted: Font:12 pt

Table 3-3 shows how Canyon's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Deleted: 5

Deleted: 5

Deleted: 5

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	32.00	0	0	0
1	2015	14,200	30.60	7	83	76
2	2016	14,321	29.20	15	84	69
3	2017	14,441	27.80	22	84	62
4	2018	14,562	26.40	30	85	55
5-year Goal	2019	14,682	25.00	38	86	48
6	2020	14,803	24.00	43	86	43
7	2021	14,978	23.00	49	87	38
8	2022	15,153	22.00	55	88	33
9	2023	15,328	21.00	62	90	28
10-year Goal	2024	15,503	20.00	68	91	23

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

4 Implemented Activities

Formatted: Font:12 pt

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

Deleted: During the project, we were able to

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

Deleted: we used

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

4.1 Itemized Activities

Formatted: Font:12 pt

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Savings of 83 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
    a. Last three rate increases:[17]
        i. 2% increase in 2015
        ii. 5% increase in 2016
        iii. 4% increase in 2017
    b. Estimated customer demand reduction of 2.2%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
    a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
    b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.

---

15 If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
16 In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
17 Correspondence with utility staff.
18 The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

Deleted: We

Deleted: we can

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
    i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

5 Summary of Savings

2023	15,328	16	90
2024	15,503	16	91

6 Suggested Activities

Formatted: Font:12 pt

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
  - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

Formatted: Font:12 pt

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications
b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
c. Estimate assumes customers will save 10% of total annual use due to the portal
   i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
   i. This was the most common percentage of residential use among participating utilities in this project.
   ii. Actual customer class demand percentages will vary by utility.
e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
f. Savings are assumed to increase along with demand as connections increase each year[19]

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Deleted: Prepared by Averitt & Associates, Inc. for the Texas Water Development Board

g. See Table 6-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	16	84	100	15	23	0	23	92
2017	25	84	110	15	23	0	23	102

2. Employ efforts to maintain water loss volumes near baseline level or below.
3. In the future, as your utility finds water and/or wastewater service rate increases necessary, such pricing signals should continue to be effective in reducing demand.

Statewide Water Conservation Quantification Project
City of Dumas Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Dumas's current water conservation activities and their quantified savings to two metrics: 1) Region A Water Plan's (Texas Water Development Board, 2016) recommended WMS supply volumes for municipal conservation, and 2) Dumas's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Dumas's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility’s service area are implemented on a micro-scale that may not be quantified. Individual households

---

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation annual reports: (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in annual TWDB water loss audits: (Total Water Loss ÷ Permanent Population) ÷ 365

and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Dumas with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

This table compares all quantified conservation activity starting in 2015 and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).[12] Refer to Tables 5-1 and 5-2 for details on these savings.

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If the utility's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

2070	389	(22)	367	75	0	75	292

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Dumas's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	162	0	0	0
1	2015	15,001	162	2	208	(13)
2	2016	15,380	161	4	211	(16)
3	2017	15,759	161	7	213	(18)
4	2018	16,139	160	9	215	(21)
5-year Goal	2019	16,518	160	12	218	(24)
6	2020	16,897	160	14	220	(26)
7	2021	17,133	160	15	223	(28)
8	2022	17,370	159	16	225	(29)
9	2023	17,606	159	18	228	(31)
10-year Goal	2024	17,842	159	20	230	(33)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for total GPCD from the utility's most recently submitted 5-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Dumas's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	28.00	0	0	0
1	2015	15,001	27.00	5	(11)	(5)
2	2016	15,380	26.00	11	(11)	0
3	2017	15,759	25.00	17	(12)	6
4	2018	16,139	24.00	24	(12)	12
5-year Goal	2019	16,518	23.00	30	(12)	18
6	2020	16,897	22.00	37	(12)	25
7	2021	17,133	21.00	44	(13)	31
8	2022	17,370	20.00	51	(13)	38
9	2023	17,606	19.00	58	(13)	45
10-year Goal	2024	17,842	18.00	65	(13)	52

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Loss of 11 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increase**
    a. Last rate increase:[17]
        i. 100% increase in 2015
    b. Estimated customer demand reduction of 20%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
    a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
    b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
    i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

6. Showerhead Distribution (SF)

a. Estimated 2,050 gallons per year per showerhead (A&N Technical Services, 2005)
b. Estimated 8,000 gallons per year for each system evaluation (A&N Technical Services, 2005)
    i. Assumed 65% savings from typical indoor and outdoor survey when only outdoor watering is evaluated (Whitcomb, 2000)
c. Approximately 22 gallons per day
d. Greater savings during peak periods
e. Lesser savings during off-peak periods
f. 20% decay rate per year attributed to customer behavior (A&N Technical Services, 2005)

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Water Rate Increases	Showerheads (SF)	TOTAL SAVINGS
2013		0.8	0.8
2014		1.3	1.3
2015	218	1.7	219.2
2016	220	1.9	222.0
2017	223	1.9	224.6
2018	225	1.9	227.3
2019	228	1.9	229.9
2020	231	1.9	232.5
2021	233	1.9	235.1
2022	236	1.9	237.7

2024	17,842	30	(13)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications
b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
c. Estimate assumes customers will save 10% of total annual use due to the portal
  i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
  i. This was the most common percentage of residential use among participating utilities in this project.
  ii. Actual customer class demand percentages will vary by utility.
e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
f. Savings are assumed to increase along with demand as connections increase each year[19]

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

g. See Table 6-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	222	(11)	211	15	24	0	24	201
2017	225	(12)	213	15	24	0	24	204
2018	227	(12)	215	15	29	0	29	202
2019	230	(12)	218	15	34	0	34	199
2020	233	(12)	220	15	43	0	43	192
2021	235	(13)	223	16	44	0	44	194
2022	238	(13)	225	16	45	0	45	196
2023	240	(13)	228	16	45	0	45	198
2024	243	(13)	230	16	46	0	46	200
2025	246	(13)	232	16	46	0	46	202
2026	248	(13)	235	17	47	0	47	204
2027	251	(14)	237	17	48	0	48	206
2028	253	(14)	240	17	48	0	48	208
2029	256	(14)	242	17	49	0	49	210
2030	259	(14)	245	17	50	0	50	212
2031	262	(14)	247	17	50	0	50	215
2032	265	(14)	250	18	51	0	51	217
2033	268	(15)	253	18	51	0	51	219
2034	270	(15)	256	18	52	0	52	222
2035	273	(15)	258	18	53	0	53	224
2036	276	(15)	261	18	53	0	53	226
2037	279	(15)	264	19	54	0	54	229
2038	282	(16)	267	19	54	0	54	231
2039	285	(16)	269	19	55	0	55	233
2040	288	(16)	272	19	56	0	56	235

1. Employ efforts to maintain water loss volumes near baseline level or below.
2. In the future, as your utility finds water and/or wastewater service rate increases necessary, such pricing signals should continue to be effective in reducing demand.

Statewide Water Conservation Quantification Project
City of Perryton Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use

[1] Equal to 811,224 acre-feet per year in conservation savings.

- Collective reporting units (CRUs) consisting of grouped utilities having a common association
- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached, after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Perryton's current water conservation activities and their quantified savings to two metrics: 1) Region A Water Plan's (Texas Water Development Board, 2016) recommended WMS supply volumes for municipal conservation, and 2) Perryton's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Perryton's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

---

[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Perryton with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).[12] Refer to Tables 5-1 and 5-2 for details on these savings.

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If the utility's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	24	(64)	(40)	12	0	12	(53)
2016	24	(65)	(41)	15	0	15	(56)

2067	34	(95)	(61)	38	0	38	(99)
2068	34	(95)	(61)	38	0	38	(100)
2069	34	(96)	(62)	39	0	39	(100)
2070	35	(97)	(62)	39	0	39	(101)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Perryton's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	215	0	0	0
1	2015	9,300	214	3	(40)	(44)
2	2016	9,386	213	7	(41)	(48)
3	2017	9,471	212	10	(41)	(52)
4	2018	9,557	211	14	(42)	(56)
5-year Goal	2019	9,642	210	18	(42)	(60)
6	2020	9,728	209	21	(43)	(64)
7	2021	9,801	208	25	(43)	(68)
8	2022	9,873	207	29	(43)	(72)
9	2023	9,946	206	33	(44)	(76)
10-year Goal	2024	10,018	205	37	(44)	(81)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for total GPCD from the utility's most recently submitted 5-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Perryton's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	23.00	0	0	0
1	2015	9,300	22.40	2	(64)	(67)
2	2016	9,386	21.80	4	(65)	(69)
3	2017	9,471	21.20	6	(66)	(72)
4	2018	9,557	20.60	8	(66)	(75)
5-year Goal	2019	9,642	20.00	11	(67)	(77)
6	2020	9,728	19.40	13	(67)	(80)
7	2021	9,801	18.80	15	(68)	(83)
8	2022	9,873	18.20	17	(68)	(86)
9	2023	9,946	17.60	20	(69)	(89)
10-year Goal	2024	10,018	17.00	22	(69)	(91)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Loss of 64 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increase**
    a. Last rate increase:[17]
        i. 13.5% increase in 2015
    b. Estimated customer demand reduction of 2.7%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
    a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
    b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
    i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Water Rate Increases	TOTAL SAVINGS
2012	0	0
2013	0	0
2014	0	0
2015	24.2	24.2
2016	24.3	24.3
2017	24.5	24.5
2018	24.6	24.6
2019	24.7	24.7
2020	24.9	24.9
2021	25.0	25.0
2022	25.2	25.2
2023	25.3	25.3
2024	25.5	25.5
2025	25.6	25.6
2026	25.8	25.8
2027	25.9	25.9
2028	26.1	26.1

2041	28.2	28.2
2042	28.4	28.4
2043	28.6	28.6
2044	28.8	28.8
2045	29.0	29.0
2046	29.2	29.2
2047	29.4	29.4
2048	29.5	29.5
2049	29.7	29.7
2050	29.9	29.9
2051	30.1	30.1
2052	30.4	30.4
2053	30.6	30.6
2054	30.8	30.8
2055	31.0	31.0
2056	31.2	31.2
2057	31.5	31.5
2058	31.7	31.7
2059	31.9	31.9
2060	32.1	32.1
2061	32.4	32.4
2062	32.6	32.6
2063	32.8	32.8
2064	33.1	33.1
2065	33.3	33.3
2066	33.6	33.6
2067	33.8	33.8
2068	34.0	34.0
2069	34.3	34.3
2070	34.5	34.5

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	23.00	0
2015	9,300	42.00	(64)
2016	9,386	42.00	(65)
2017	9,471	42.00	(66)
2018	9,557	42.00	(66)
2019	9,642	42.00	(67)
2020	9,728	42.00	(67)
2021	9,801	42.00	(68)
2022	9,873	42.00	(68)
2023	9,946	42.00	(69)
2024	10,018	42.00	(69)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications

b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)

c. Estimate assumes customers will save 10% of total annual use due to the portal

  i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)

d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB

  i. This was the most common percentage of residential use among participating utilities in this project.

  ii. Actual customer class demand percentages will vary by utility.

e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand

f. Savings are assumed to increase along with demand as connections increase each year[19]

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

g. See Table 6-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	24	(65)	(41)	12	15	0	15	(44)
2017	24	(66)	(41)	12	15	0	15	(44)
2018	25	(66)	(42)	12	18	0	18	(48)
2019	25	(67)	(42)	12	22	0	22	(51)
2020	25	(67)	(43)	12	28	0	28	(58)

Region B Individual Reports

Statewide Water Conservation Quantification Project
City of Wichita Falls Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

> after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Wichita Falls' current water conservation activities and their quantified savings to two metrics: 1) Region B Water Plan's (Texas Water Development Board, 2016a) recommended WMS supply volumes for municipal conservation, and 2) Wichita Falls' own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Wichita Falls' most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD [7] consumption and water loss GPCD.[8] [9]

---

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Wichita Falls with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	1,072	624	1,696	649	0	649	1,047
2016	1,073	625	1,698	812	0	812	886
2017	1,143	626	1,769	812	0	812	957

2067	1,194	703	1,897	1,461	0	1,461	436
2068	1,196	704	1,900	1,461	0	1,461	438
2069	1,198	705	1,902	1,461	0	1,461	441
2070	1,199	706	1,905	1,461	0	1,461	444

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Wichita Falls' quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	153	0	0	0
1	2015	106,876	155	(94)	1,696	1,790
2	2016	107,068	158	(188)	1,698	1,886
3	2017	107,260	160	(282)	1,769	2,051
4	2018	107,451	163	(377)	1,771	2,147
5-year Goal	2019	107,643	165	(471)	1,773	2,244
6	2020	107,835	164	(433)	1,775	2,208
7	2021	108,228	163	(395)	1,778	2,173
8	2022	108,621	162	(357)	1,781	2,138
9	2023	109,015	161	(318)	1,784	2,102
10-year Goal	2024	109,408	160	(280)	1,787	2,066

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for total GPCD from the utility's most recently submitted 5-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Wichita Falls' most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	18.00	0	0	0
1	2015	106,876	19.20	(47)	624	671
2	2016	107,068	20.40	(94)	625	719
3	2017	107,260	21.60	(141)	626	767
4	2018	107,451	22.80	(188)	628	816
5-year Goal	2019	107,643	24.00	(236)	629	864
6	2020	107,835	24.00	(236)	630	866
7	2021	108,228	24.00	(237)	632	869
8	2022	108,621	24.00	(238)	634	872
9	2023	109,015	24.00	(239)	637	875
10-year Goal	2024	109,408	24.00	(240)	639	879

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic 5-year average for water loss GPCD from the utility's most recently submitted 5-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Savings of 624 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increase**
    a. Last rate increase:[17]
        i. 53% increase in 2014
    b. Estimated customer demand reduction of 10.6%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Twice-a-week Outdoor Watering Restriction Ordinance**
    a. Estimated savings of 8.42% of total utility demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and the National Wildlife Federation, 2015)
    b. All savings estimates grow each year at the same rate demand figures for the utility grow in the regional water plan.

6. **Advanced Metering Infrastructure (AMI) with Customer Engagement Portal**

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

a. MyH2O: My Water My Way
b. Implemented in 2017
c. Estimated savings of 68.9 MG in 2017
    i. Specific utility results may vary based on portal features and notifications
d. Assumes 20% of residential customers are using and saving water due to the portal (Westin Engineering, 2015)
e. Assumes customers save 10% of total annual use due to the portal
    i. Savings estimate is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
f. Residential customers' use makes up approximately 61% of all retail customers' use based on utility profile information submitted to the TWDB
g. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.22% of total demand
    i. Savings are assumed to increase along with demand as connections increase each year[19]

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	2x Watering Ordinance	AMI with Customer Portal	Water Rate Increase	TOTAL SAVINGS
2012				0
2013				0
2014			597	597
2015	475		598	1,072
2016	475		598	1,073
2017	475	68.9	598	1,143
2018	476	68.9	599	1,143
2019	476	69.0	599	1,144
2020	476	69.0	600	1,145
2021	477	69.1	600	1,146
2022	477	69.1	600	1,146
2023	477	69.2	601	1,147
2024	478	69.2	601	1,148
2025	478	69.2	602	1,149
2026	478	69.3	602	1,150
2027	479	69.3	602	1,150
2028	479	69.4	603	1,151
2029	479	69.4	603	1,152
2030	480	69.5	604	1,153
2031	480	69.5	604	1,153
2032	480	69.5	604	1,154
2033	480	69.6	604	1,154
2034	480	69.6	605	1,154
2035	480	69.6	605	1,155
2036	481	69.6	605	1,155
2037	481	69.7	605	1,156
2038	481	69.7	606	1,156
2039	481	69.7	606	1,157
2040	481	69.8	606	1,157
2041	482	69.8	606	1,158
2042	482	69.8	607	1,159
2043	482	69.9	607	1,159
2044	483	69.9	608	1,160
2045	483	70.0	608	1,161
2046	483	70.0	608	1,162
2047	483	70.1	609	1,162
2048	484	70.1	609	1,163
2049	484	70.1	609	1,164
2050	484	70.2	610	1,164
2051	485	70.3	611	1,166
2052	486	70.4	612	1,168
2053	487	70.5	613	1,170
2054	487	70.6	614	1,171
2055	488	70.7	614	1,173
2056	489	70.8	615	1,175
2057	490	70.9	616	1,177
2058	490	71.0	617	1,179
2059	491	71.2	618	1,180
2060	492	71.3	619	1,182
2061	493	71.4	620	1,184
2062	493	71.5	621	1,186
2063	494	71.6	622	1,187
2064	495	71.7	623	1,189
2065	495	71.8	624	1,191
2066	496	71.9	625	1,193
2067	497	72.0	625	1,194
2068	498	72.1	626	1,196
2069	498	72.2	627	1,198
2070	499	72.3	628	1,199

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction (MG)
Baseline	-	18.00	0
2015	106,876	2.00	624
2016	107,068	2.00	625
2017	107,260	2.00	626
2018	107,451	2.00	628
2019	107,643	2.00	629
2020	107,835	2.00	630
2021	108,228	2.00	632
2022	108,621	2.00	634
2023	109,015	2.00	637
2024	109,408	2.00	639

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Rain Barrels
    - **a.** In Region B, utilities could save approximately 16.5 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
    - **b.** Estimated 10-year useful life for most barrels

Region C Individual Reports

Statewide Water Conservation Quantification Project
City of Addison Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Addison's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Addison's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Addison's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Addison with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	23.1	6	29	12	4	16	13
2016	41.7	6	47	14	5	20	27
2017	42.5	5	48	14	7	21	27
2018	43.3	5	49	17	8	25	24
2019	44.2	5	50	20	9	29	21
2020	45.0	5	50	26	10	36	14
2021	45.8	5	51	28	10	38	13

2058	77.2	9	87	121	0	121	(35)
2059	78.1	9	88	124	0	124	(36)
2060	79.0	10	89	126	0	126	(38)
2061	79.8	10	89	129	0	129	(39)
2062	80.7	10	90	131	0	131	(41)
2063	81.6	10	91	134	0	134	(43)
2064	82.5	10	92	137	0	137	(44)
2065	83.3	10	93	139	0	139	(46)
2066	84.2	10	94	142	0	142	(48)
2067	85.1	10	95	145	0	145	(49)
2068	86.0	10	96	147	0	147	(51)
2069	86.8	10	97	150	0	150	(53)
2070	87.7	11	98	153	0	153	(54)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Addison's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	208	0	0	0
1	2015	15,407	206	13	29	15
2	2016	15,233	203	27	47	21
3	2017	15,060	201	40	48	8
4	2018	14,886	198	52	49	(3)
5-year Goal	2019	14,713	196	64	50	(15)
6	2020	14,539	196	65	50	(14)
7	2021	14,828	196	67	51	(16)
8	2022	15,117	195	70	52	(17)
9	2023	15,407	195	72	53	(19)
10-year Goal	2024	15,696	195	74	54	(20)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Addison's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	14.00	0	0	0
1	2015	15,407	13.80	1	6	4
2	2016	15,233	13.60	2	6	3
3	2017	15,060	13.40	3	5	2
4	2018	14,886	13.20	4	5	1
5-year Goal	2019	14,713	13.00	5	5	0
6	2020	14,539	13.00	5	5	0
7	2021	14,828	13.00	5	5	0
8	2022	15,117	13.00	6	6	0
9	2023	15,407	13.00	6	6	0
10-year Goal	2024	15,696	13.00	6	6	0

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
   a. Easy-to-use website with conservation tips and water rates
   b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
   a. The utility engages the public in many ways including:
      i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
   a. Savings of 13 MG annually in 2015
   b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
   c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
   d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
   a. Last rate increases:[17]
      i. 6.4% increase in 2015
      ii. 4.9% increase in 2016
   b. Estimated customer demand reduction of 2.26%
   c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
      i. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Water Rate Increase	TOTAL SAVINGS
2009		0
2010		0
2011		0
2012		0
2013		0
2014		0
2015	23	23.1
2016	42	41.7
2017	42	42.5
2018	43	43.3
2019	44	44.2
2020	45	45.0
2021	46	45.8
2022	47	46.7
2023	47	47.5

2024	15,696	13.00	6

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - o The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
   a. Potentially 8% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
      i. Average Region C savings
      ii. Specific percentage of outdoor usage unknown for your utility at this time
   b. Savings could be 145 MG per year with current demand.
   c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	42	6	47	145	14	5	20	172
2017	42	5	48	148	14	7	21	175
2018	43	5	49	151	17	8	25	174
2019	44	5	50	154	20	9	29	174
2020	45	5	50	156	26	10	36	171
2021	46	5	51	159	28	10	38	172
2022	47	6	52	162	31	10	41	174
2023	47	6	53	165	33	10	43	175
2024	48	6	54	168	36	10	45	177
2025	49	6	55	171	38	10	48	178
2026	50	6	56	174	41	10	50	179
2027	51	6	57	177	43	10	53	181
2028	52	6	58	180	45	10	55	182
2029	52	6	59	183	48	10	58	184
2030	53	6	60	185	50	10	60	185
2031	54	6	61	188	53	9	62	187
2032	55	7	62	191	56	8	64	189
2033	56	7	63	194	59	7	66	191
2034	57	7	63	197	62	6	68	192
2035	58	7	64	200	65	5	70	194
2036	58	7	65	203	68	4	72	196
2037	59	7	66	206	71	3	74	198
2038	60	7	67	209	74	2	76	200
2039	61	7	68	212	77	1	78	202
2040	62	7	69	215	80	0	80	203

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[19]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

3. Rain Barrels
   a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
   b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of Allen Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Allen's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Allen's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Allen's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8,9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

---

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Allen with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	827	171	998	96	15	111	887

2070	1,058	228	1,286	385	0	385	902

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Allen's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	165	0	0	0
1	2015	93,568	164	34	998	964
2	2016	94,854	163	69	1,005	936
3	2017	96,141	162	105	1,011	906
4	2018	97,427	161	142	1,018	875
5-year Goal	2019	98,714	160	180	1,024	844
6	2020	100,000	158	241	1,030	789
7	2021	100,500	157	301	1,035	734
8	2022	101,000	155	361	1,040	679
9	2023	101,500	154	422	1,045	623
10-year Goal	2024	102,000	152	484	1,050	566

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Allen's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	17.00	0	0	0
1	2015	93,568	16.80	7	171	164
2	2016	94,854	16.60	14	173	159
3	2017	96,141	16.40	21	175	154
4	2018	97,427	16.20	28	178	149
5-year Goal	2019	98,714	16.00	36	180	144
6	2020	100,000	15.80	44	183	139
7	2021	100,500	15.60	51	183	132
8	2022	101,000	15.40	59	184	125
9	2023	101,500	15.20	67	185	119
10-year Goal	2024	102,000	15.00	74	186	112

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Robust Public Education Effort**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, school visits, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Savings of 171 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
    a. Last rate increases:[17]
        i. 5.8% increase in 2014
        ii. 5.8% increase in 2015
    b. Estimated customer demand reduction of 2.3%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Twice-a-week Outdoor Watering Restriction Ordinance**
    a. Estimated savings of 8.84% of total utility demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and the National Wildlife Federation, 2015)
    b. All savings estimates grow each year at the same rate demand figures for the utility grow in the regional water plan.

6. **Outdoor Landscape Evaluations (SF)**

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

a. 160 outdoor evaluations performed since 2015
b. Estimated 8,000 gallons per year for each system evaluation (A&N Technical Services, 2005)
    i. Assumed 65% savings from typical indoor and outdoor survey when only outdoor watering is evaluated (Whitcomb, 2000)
c. Approximately 22 gallons per day
d. Greater savings during peak periods
e. Lesser savings during off-peak periods
f. 20% decay rate per year attributed to customer behavior (A&N Technical Services, 2005)

7. Rainwater Barrels

a. In Region C, estimated savings of 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
b. Estimated 10-year useful life for most barrels

8. High Efficiency (HE) Toilet Replacement Program (SF)

a. Quantified program efforts back to 2004
b. Used savings estimate for replacing 3.5 gallons per flush (gpf) toilet with 1.6 gpf toilet for years 2004 – 2013
c. Used savings estimate for replacing 3.5 gallons per flush (gpf) toilet with 1.28 gpf toilet for years 2014 – 2015
d. Replacements per year provided by staff
e. Estimated savings of 8,440 gallons per year per toilet for replacement with 1.6 gpf toilet model (A&N Technical Services, 2005)
f. Estimated savings of 10,390 gallons per year per toilet for replacement with 1.28 gpf toilet (A&N Technical Services, 2005)
g. Savings carry on indefinitely because replacement toilet will be as efficient

9. Clotheswasher Replacement Program (SF)

a. 4,118 rebates issued from 2004 – 2015
b. Rebates per year provided by staff
c. Estimated 7,030 gallons per year per washer (A&N Technical Services, 2005; THELMA, 1997)
d. 11-year useful life

10. Audits by Ordinance (MF, ICI, and HOA)

a. Staff estimated 19% reduction when audits performed
b. Demand for ICI customer class was 783 MG in 2012
c. Average commercial customer use 0.48 MG (783 MG/1,617 customers)
d. 19% reduction per customer = 0.0912 MG savings per customer audit
e. 0.912 MG x 350 audits per year = 33.9 MG of savings annually
f. Increases over time with continuing population and ICI connection rate increases

11. Custom Rebates

i. Not quantified — Did not have sufficient information on devices that were rebated.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	2x Watering Ordinance	Rain Barrels	Outdoor Landscape Evaluations	HE Toilet Rebates (SF)	HE Clothes Washer Rebates (SF)	Water Rate Increases	Audits by Ordinance (ICI)	Custom Rebates*	TOTAL SAVINGS
2009		0.18		9.9	17.6		34		62
2010		0.26		11.6	20.4		34		66
2011		0.33		12.8	22.4		34		70
2012		0.36		15.5	24.4		35		75
2013		0.42		19.5	26.5		35		81

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	17.00	0
2015	93,568	12.00	171
2016	94,854	12.00	173
2017	96,141	12.00	175
2018	97,427	12.00	178
2019	98,714	12.00	180
2020	100,000	12.00	183
2021	100,500	12.00	183
2022	101,000	12.00	184
2023	101,500	12.00	185
2024	102,000	12.00	186

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications
b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
c. Estimate assumes customers will save 10% of total annual use due to the portal
    i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    i. This was the most common percentage of residential use among participating utilities in this project.
    ii. Actual customer class demand percentages will vary by utility.
e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
f. Savings are assumed to increase along with demand as connections increase each year[19]

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

g. See Table 6-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	832	173	1,005	88	119	19	138	955
2017	836	175	1,011	89	119	22	142	958

Statewide Water Conservation Quantification Project
City of Arlington Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common

[1] Equal to 811,224 acre-feet per year in conservation savings.

association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached, after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Arlington's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Arlington's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Arlington's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD [7] consumption and water loss GPCD.[8] [9]

---

[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.
[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.
[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365
[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Arlington with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with

---

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. **Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.**

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	497	135	632	137	49	186	446
2016	724	136	860	172	61	232	628

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Arlington's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	159	0	0	0
1	2015	370,367	157	216	632	416
2	2016	373,839	156	437	860	424
3	2017	377,310	154	661	1,152	491
4	2018	380,782	153	890	1,156	266
5-year Goal	2019	384,253	151	1,122	1,160	38
6	2020	387,725	149	1,359	1,164	(194)
7	2021	390,227	148	1,595	1,168	(427)
8	2022	392,729	146	1,835	1,173	(662)
9	2023	395,231	145	2,077	1,178	(900)
10-year Goal	2024	397,733	143	2,323	1,182	(1,140)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Arlington's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	16.00	0	0	0
1	2015	370,367	15.80	27	135	108
2	2016	373,839	15.60	55	136	82
3	2017	377,310	15.40	83	138	55
4	2018	380,782	15.20	111	139	28
5-year Goal	2019	384,253	15.00	140	140	0
6	2020	387,725	14.80	170	142	(28)
7	2021	390,227	14.60	199	142	(57)
8	2022	392,729	14.40	229	143	(86)
9	2023	395,231	14.20	260	144	(115)
10-year Goal	2024	397,733	14.00	290	145	(145)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Savings of 135 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
    a. Last rate increases:[17]
        i. 10.1% increase in 2015
        ii. 4.3% increase in 2016
    b. Estimated customer demand reduction of 3.0%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years

5. **Advanced Metering Infrastructure (AMI) with Customer Engagement Portal**
    a. Texas A&M AgriLife Research Extension and Texas Water Resources Institute web-based customer portal
    b. Pilot implemented in 2014
    c. Estimated savings of 289 MG in 2017

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

d. Assumes a full 20% of residential customers are now using and saving water due to the portal after continued implementation from 2014 – 2016
e. Assumes customers save 10% of total annual use due to the portal
    i. Savings estimate is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
    ii. Texas Water Resources Institute reported a 12.85% reduction over one year, however, savings reduction decreased the following winter (Texas A&M and Texas Water Resources Institute, 2016).
f. Residential customers' use makes up approximately 72% of all retail customers' use based on utility profile information submitted to the TWDB
g. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.43% of total demand
h. Savings are assumed to increase along with demand as connections increase each year[19]

6. Outdoor Landscape Evaluations (SF) — W.I.S.E. Guys Program
a. 500 outdoor evaluations performed since 2012
b. Estimated 8,000 gallons per year for each system evaluation (A&N Technical Services, 2005)
    i. Assumed 65% savings from typical indoor and outdoor survey when only outdoor watering is evaluated (Whitcomb, 2000)
c. Approximately 22 gallons per day
d. Greater savings during peak periods
e. Lesser savings during off-peak periods
b. 20% decay rate per year attributed to customer behavior (A&N Technical Services, 2005)

7. WaterWise Take-home Kits
a. Estimated savings of 7,384 gallons per year per kit (Frontier Associates, 2015)
b. Conservative 5-year useful life for all items in kit
c. 15% adoption rate assumed

8. Save Water Co. Commercial, Multi-family and Hotel Programs[20]
a. Project initiated in service area in 2015
b. Save Water completed work on 303 multi-family units in 2016
c. Average monthly savings of 913,742 gallons
d. Annualized savings of 11 MG for the life of the retrofitted fixtures
e. This study estimates a lifespan of 25 years for high-efficiency toilet replacements, five years for kitchen aerators and similar devices.

---

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.
[20] Savings figures and units serviced based on personal email communication with Kurt Goedrich, December 1, 2016.

f. Save Water Co. performs monthly meter readings before and after installation to quantify savings.
g. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets and replacing sink aerators.

9. High Efficiency (HE) Toilet Replacement Program (SF)

a. Estimated 10,390 gallons per year per toilet (A&N Technical Services, 2005)
b. Number of toilets replaced per year provided by utility staff
c. Savings carry on indefinitely because replacement toilet will be as efficient

10. Showerhead Distribution (SF)

a. Estimated 2,050 gallons per year per showerhead (A&N Technical Services, 2005)
b. Number of showerheads replaced per year provided by utility staff
c. 5-year useful life
    i. If distributed after 2009, plumbing code will require that replacement is equally as efficient, so savings will carry forward indefinitely

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	W.I.S.E. Guys Audits	WaterWise Take-home Kits	HE Toilet Rebates (SF)	Low Flow Showerheads (SF)	Water Rate Increases	AMI with Customer Portal	Save Water Co. Program	TOTAL SAVINGS
2009			6.2	1.8				8
2010			12.5	3.7				16
2011			18.7	5.5				24
2012	0.8	0.6	24.9	7.4				34
2013	1.4	1.0	31.2	9.2				43
2014	1.9	1.3	37.4	11.1				52
2015	2.2	1.6	43.6	12.9	428		9	497
2016	2.4	1.7	49.9	14.8	644		11	724
2017	1.6	1.1	49.9	14.8	647	289	11	1,014
2018	1.0	0.7	49.9	14.8	649	290	11	1,017
2019	0.5	0.3	49.9	14.8	652	291	11	1,019
2020	0.2	0.1	49.9	14.8	654	292	11	1,023
2021			49.9	14.8	657	293	11	1,026

2024	397,733	15.00	145

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
  - **a.** Potentially 7.58% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
  - **b.** Savings could be 1,628 MG per year with current demand.
  - **c.** See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	724	136	860	1,628	172	61	232	2,256
2017	1,014	138	1,152	1,634	172	73	245	2,541
2018	1,017	139	1,156	1,641	206	85	291	2,505
2019	1,019	140	1,160	1,647	241	97	338	2,469
2020	1,023	142	1,164	1,654	309	109	418	2,399
2021	1,026	142	1,168	1,660	331	109	441	2,388
2022	1,030	143	1,173	1,666	353	109	463	2,377
2023	1,033	144	1,178	1,673	376	109	485	2,366
2024	1,037	145	1,182	1,679	398	109	507	2,355
2025	1,041	146	1,187	1,686	420	109	529	2,344
2026	1,045	147	1,192	1,692	442	109	551	2,333
2027	1,048	148	1,196	1,699	464	109	573	2,322
2028	1,052	149	1,201	1,705	486	109	595	2,311
2029	1,056	150	1,205	1,712	508	109	617	2,300
2030	1,059	151	1,210	1,718	530	109	639	2,289
2031	1,060	151	1,211	1,719	549	98	648	2,282
2032	1,060	151	1,211	1,720	569	87	656	2,275
2033	1,061	152	1,212	1,720	588	76	664	2,268
2034	1,061	152	1,213	1,721	607	66	673	2,262
2035	1,061	152	1,214	1,722	626	55	681	2,255
2036	1,062	153	1,214	1,723	645	44	689	2,248
2037	1,062	153	1,215	1,723	665	33	697	2,241
2038	1,063	153	1,216	1,724	684	22	706	2,234
2039	1,063	154	1,217	1,725	703	11	714	2,228
2040	1,064	154	1,218	1,726	722	0	722	2,221

2. Rain Barrels
  - **a.** In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
  - **b.** Estimated 10-year useful life for most barrels

TWDB Statewide Water Conservation Quantification Project
City of Balch Springs Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were to be completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common

[1] Equal to 811,224 acre-feet per year in conservation savings.

association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached, after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2015j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, we first engaged with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

We then quantified each utility's conservation activities through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. Individual reports distributed to each participating utility detail these attributes. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Balch Springs' current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Balch Springs' own five- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The five- and 10-year goals in Balch Springs' most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD [7] consumption and water loss GPCD.[8] [9]

---

[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.
[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.
[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. We are not aware of all activities that are ongoing. Some activities within a utility's service area are implemented on a micro-scale that we cannot yet quantify. Individual households and businesses may be implementing conservation measures that we do not know about and therefore cannot include in this report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because we used a single year (2015) value for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures we have carried forward in our model because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. Our approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in million gallons) in Regional Water Plan

Table 3-1 shows a 2070 outlook for Balch Springs with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

---

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, excluding savings from water loss reduction. Because the regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, we have quantified utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

---

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	21.8	(9)	13	1	2	3	10
2016	21.9	(9)	13	2	3	4	9
2017	22.1	(9)	13	2	3	5	8
2018	22.2	(9)	13	2	4	6	7
2019	22.3	(9)	13	2	4	6	6
2020	22.4	(10)	13	3	5	7	5
2021	22.5	(10)	13	3	5	8	5
2022	22.6	(10)	13	4	5	8	5

2066	30.2	(14)	16	23	0	23	(7)
2067	30.4	(14)	16	23	0	23	(7)
2068	30.6	(14)	16	24	0	24	(7)
2069	30.8	(15)	16	24	0	24	(8)
2070	31.0	(15)	16	25	0	25	(8)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Balch Springs' quantified savings from its implemented activities compare with five- and goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match five- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	84	0	0	0
1	2015	24,002	84	(2)	13	15
2	2016	24,486	84	(4)	13	17
3	2017	24,970	85	(5)	13	18
4	2018	25,455	85	(7)	13	20
5-year Goal	2019	25,939	85	(9)	13	22
6	2020	26,423	86	(19)	13	32
7	2021	26,679	87	(29)	13	42
8	2022	26,934	88	(39)	13	52
9	2023	27,190	89	(50)	13	62
10-year Goal	2024	27,446	90	(60)	13	73

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Balch Springs' most recent water loss audit compares with five- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match five- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	Baseline	-	7.00	0	0	0
1	2015	24,002	7.00	0	(9)	(9)
2	2016	24,486	7.00	0	(9)	(9)
3	2017	24,970	7.00	0	(9)	(9)
4	2018	25,455	7.00	0	(9)	(9)
5-year Goal	2019	25,939	7.00	0	(9)	(9)
6	2020	26,423	7.20	(2)	(10)	(8)
7	2021	26,679	7.40	(4)	(10)	(6)
8	2022	26,934	7.60	(6)	(10)	(4)
9	2023	27,190	7.80	(8)	(10)	(2)
10-year Goal	2024	27,446	8.00	(10)	(10)	0

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). During the project, we were able to survey several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, we used a 50/50 savings split when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Loss of 9 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Conservation Pricing**
    a. Tiered rate structure in place saves approximately 2.5% of total demand
        i. Savings is cumulative and based on more than one source[17] (U.S. EPA, 1998; TWDB, 2013)

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] We estimate 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, we can determine the savings for lower or higher percentage increases.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Conservation Pricing	TOTAL SAVINGS
2009		0
2010		0
2011	21.3	21.3
2012	21.5	21.5
2013	21.6	21.6
2014	21.7	21.7
2015	21.8	21.8
2016	21.9	21.9
2017	22.1	22.1
2018	22.2	22.2
2019	22.3	22.3
2020	22.4	22.4
2021	22.5	22.5
2022	22.6	22.6
2023	22.8	22.8
2024	22.9	22.9
2025	23.0	23.0
2026	23.1	23.1
2027	23.2	23.2
2028	23.4	23.4

2030	23.6	23.6
2031	23.7	23.7
2032	23.9	23.9
2033	24.0	24.0
2034	24.1	24.1
2035	24.3	24.3
2036	24.4	24.4
2037	24.6	24.6
2038	24.7	24.7
2039	24.8	24.8
2040	25.0	25.0
2041	25.2	25.2
2042	25.4	25.4
2043	25.5	25.5
2044	25.7	25.7
2045	25.9	25.9
2046	26.1	26.1
2047	26.3	26.3
2048	26.5	26.5
2049	26.7	26.7
2050	26.8	26.8
2051	27.0	27.0
2052	27.3	27.3
2053	27.5	27.5
2054	27.7	27.7
2055	27.9	27.9
2056	28.1	28.1
2057	28.3	28.3
2058	28.5	28.5
2059	28.7	28.7
2060	28.9	28.9
2061	29.1	29.1
2062	29.3	29.3
2063	29.5	29.5
2064	29.8	29.8
2065	30.0	30.0
2066	30.2	30.2
2067	30.4	30.4
2068	30.6	30.6
2069	30.8	30.8
2070	31.0	31.0

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	7.00	0
2015	24,002	8.00	(9)
2016	24,486	8.00	(9)
2017	24,970	8.00	(9)
2018	25,455	8.00	(9)
2019	25,939	8.00	(9)
2020	26,423	8.00	(10)
2021	26,679	8.00	(10)
2022	26,934	8.00	(10)
2023	27,190	8.00	(10)
2024	27,446	8.00	(10)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
   a. Potentially 8% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
      i. Average Region C savings
      ii. Specific percentage of outdoor usage unknown for your utility at this time
   b. Savings could be 70 MG per year with current demand.
   c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	22	(9)	13	70	2	3	4	79
2017	22	(9)	13	71	2	3	5	79
2018	22	(9)	13	71	2	4	6	78
2019	22	(9)	13	71	2	4	6	78
2020	22	(10)	13	72	3	5	7	77
2021	23	(10)	13	72	3	5	8	77
2022	23	(10)	13	72	4	5	8	77
2023	23	(10)	13	73	4	5	8	77
2024	23	(10)	13	73	4	5	9	77
2025	23	(10)	13	74	5	5	9	77
2026	23	(10)	13	74	5	5	9	77
2027	23	(10)	13	74	5	5	10	78
2028	23	(10)	13	75	6	5	10	78
2029	23	(10)	13	75	6	5	10	78
2030	24	(11)	13	75	6	5	11	78
2031	24	(11)	13	76	7	4	11	78
2032	24	(11)	13	76	7	4	11	79
2033	24	(11)	13	77	7	3	11	79
2034	24	(11)	13	77	8	3	10	80
2035	24	(11)	13	78	8	2	10	81
2036	24	(11)	13	78	9	2	10	81
2037	25	(11)	13	79	9	1	10	82
2038	25	(11)	13	79	9	1	10	82
2039	25	(11)	13	80	10	0	10	83
2040	25	(12)	13	80	10	0	10	83

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[18]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility’s WMS supply volumes targets.

[18] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

3. Water Rate Increase
    a. For every 10% increase, estimated savings could be 2% of utility total demand.
    b. Approximately 18 MG of savings per year with current demand
    c. Savings is cumulative and based on more than one source[19] (U.S. EPA, 1998; Whitcomb, 1999)
    d. See Table 6-3 for potential savings from this measure compared with the utility's conservation goals.

[19] We estimate 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, we can determine the savings for lower or higher percentage increases.

Table 6-3. Current Savings + Potential Savings from 10% Water Rate Increase (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Water Rate Increase	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

4. Rain Barrels
    a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
    b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of Bonham Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Bonham's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Bonham's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Bonham's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.
[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365
[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.
[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Bonham with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-1.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Bonham's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-		0	0	0
1	2015	11,456	29	(120)	(21)	100
2	2016	11,685	58	(246)	(21)	224
3	2017	11,915	86	(376)	(22)	354
4	2018	12,144	115	(511)	(22)	488
5-year Goal	2019	12,374	144	(650)	(23)	628
6	2020	12,603	143	(660)	(23)	637
7	2021	12,943	143	(675)	(24)	651
8	2022	13,282	142	(689)	(24)	665
9	2023	13,622	142	(704)	(25)	679
10-year Goal	2024	13,962	141	(719)	(25)	693

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Bonham's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-1 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-		0	0	0
1	2015	11,456	4.00	(17)	(21)	(4)
2	2016	11,685	8.00	(34)	(21)	13
3	2017	11,915	12.00	(52)	(22)	30
4	2018	12,144	16.00	(71)	(22)	49
5-year Goal	2019	12,374	20.00	(90)	(23)	68
6	2020	12,603	19.80	(91)	(23)	68
7	2021	12,943	19.60	(93)	(24)	69
8	2022	13,282	19.40	(94)	(24)	70
9	2023	13,622	19.20	(95)	(25)	71
10-year Goal	2024	13,962	19.00	(97)	(25)	71

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Loss of 21 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.

5 Summary of Savings

Table 5-1. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	20.00	0
2015	11,456	25.00	(21)
2016	11,685	25.00	(21)
2017	11,915	25.00	(22)
2018	12,144	25.00	(22)
2019	12,374	25.00	(23)
2020	12,603	25.00	(23)
2021	12,943	25.00	(24)
2022	13,282	25.00	(24)
2023	13,622	25.00	(25)
2024	13,962	25.00	(25)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs
    - Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
    - **a.** Potentially 6.11% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
    - **b.** Savings could be 36 MG per year with current demand.
    - **c.** See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	0	(21)	(21)	36	1	5	6	9
2017	0	(22)	(22)	37	1	6	7	8
2018	0	(22)	(22)	38	2	7	9	8
2019	0	(23)	(23)	39	2	8	10	7
2020	0	(23)	(23)	40	2	9	11	6
2021	0	(24)	(24)	41	3	9	11	6
2022	0	(24)	(24)	42	3	8	11	7
2023	0	(25)	(25)	43	3	7	11	8
2024	0	(25)	(25)	44	4	7	10	8
2025	0	(26)	(26)	45	4	6	10	9
2026	0	(27)	(27)	46	4	6	10	9
2027	0	(27)	(27)	47	5	5	10	10
2028	0	(28)	(28)	48	5	4	9	11
2029	0	(29)	(29)	49	5	4	9	11
2030	0	(29)	(29)	50	6	3	9	12
2031	0	(30)	(30)	52	6	3	9	12
2032	0	(31)	(31)	53	7	3	9	13
2033	0	(32)	(32)	55	7	2	9	13
2034	0	(34)	(34)	57	8	2	10	14
2035	0	(35)	(35)	59	8	2	10	14
2036	0	(36)	(36)	60	9	1	10	15
2037	0	(37)	(37)	62	9	1	10	15
2038	0	(38)	(38)	64	10	1	11	15
2039	0	(39)	(39)	66	11	0	11	16
2040	0	(40)	(40)	68	11	0	11	16

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications

b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)

c. Estimate assumes customers will save 10% of total annual use due to the portal

   i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)

d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB

   i. This was the most common percentage of residential use among participating utilities in this project.

   ii. Actual customer class demand percentages will vary by utility.

e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
f. Savings are assumed to increase along with demand as connections increase each year[17]
g. See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	0	(21)	(21)	8	1	5	6	(20)
2017	0	(22)	(22)	8	1	6	7	(21)
2018	0	(22)	(22)	8	2	7	9	(22)
2019	0	(23)	(23)	9	2	8	10	(24)
2020	0	(23)	(23)	9	2	9	11	(26)
2021	0	(24)	(24)	9	3	9	11	(26)
2022	0	(24)	(24)	9	3	8	11	(26)
2023	0	(25)	(25)	9	3	7	11	(26)

2026	0	(27)	(27)	10	4	6	10	(26)
2027	0	(27)	(27)	10	5	5	10	(27)
2028	0	(28)	(28)	11	5	4	9	(27)
2029	0	(29)	(29)	11	5	4	9	(27)
2030	0	(29)	(29)	11	6	3	9	(27)
2031	0	(30)	(30)	11	6	3	9	(28)
2032	0	(31)	(31)	12	7	3	9	(29)
2033	0	(32)	(32)	12	7	2	9	(30)
2034	0	(34)	(34)	12	8	2	10	(31)
2035	0	(35)	(35)	13	8	2	10	(32)
2036	0	(36)	(36)	13	9	1	10	(33)
2037	0	(37)	(37)	14	9	1	10	(34)
2038	0	(38)	(38)	14	10	1	11	(35)
2039	0	(39)	(39)	14	11	0	11	(35)
2040	0	(40)	(40)	15	11	0	11	(36)

3. Water Rate Increase
   a. For every 10% increase, estimated savings could be 2% of utility total demand.
   b. Approximately 12 MG of savings per year with current demand
   c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
   d. See Table 6-3 for potential savings from this measure compared with the utility's conservation goals.

[17] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

Table 6-3. Current Savings + Potential Savings from 10% Water Rate Increase (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Water Rate Increase	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	0	(21)	(21)	12	1	5	6	(16)
2017	0	(22)	(22)	12	1	6	7	(17)
2018	0	(22)	(22)	13	2	7	9	(18)
2019	0	(23)	(23)	13	2	8	10	(20)
2020	0	(23)	(23)	13	2	9	11	(21)
2021	0	(24)	(24)	14	3	9	11	(21)
2022	0	(24)	(24)	14	3	8	11	(21)

2024	0	(25)	(25)	14	4	7	10	(21)
2025	0	(26)	(26)	15	4	6	10	(21)
2026	0	(27)	(27)	15	4	6	10	(21)
2027	0	(27)	(27)	15	5	5	10	(22)
2028	0	(28)	(28)	16	5	4	9	(22)
2029	0	(29)	(29)	16	5	4	9	(22)
2030	0	(29)	(29)	16	6	3	9	(22)
2031	0	(30)	(30)	17	6	3	9	(22)
2032	0	(31)	(31)	17	7	3	9	(23)
2033	0	(32)	(32)	18	7	2	9	(24)
2034	0	(34)	(34)	19	8	2	10	(25)
2035	0	(35)	(35)	19	8	2	10	(25)
2036	0	(36)	(36)	20	9	1	10	(26)
2037	0	(37)	(37)	20	9	1	10	(27)
2038	0	(38)	(38)	21	10	1	11	(28)
2039	0	(39)	(39)	22	11	0	11	(28)
2040	0	(40)	(40)	22	11	0	11	(29)

4. Rain Barrels
   a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
   b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of Carrollton Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 20156j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Carrollton's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Carrollton's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Carrollton's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.
[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365
[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.
[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Carrollton with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

---

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	0	(47)	(47)	46	17	63	(110)
2016	62	(47)	15	57	21	78	(64)

2070	119	(47)	72	298	0	298	(226)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Carrollton's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	Baseline	-	170	0	0	0
1	2015	128,353	170	9	(47)	(56)
2	2016	128,451	170	19	15	(4)
3	2017	128,549	169	28	76	48
4	2018	128,648	169	38	76	38
5-year Goal	2019	128,746	169	47	76	29
6	2020	128,844	169	66	76	10
7	2021	128,877	168	85	76	(9)
8	2022	128,910	168	104	76	(28)
9	2023	128,944	167	122	76	(47)
10-year Goal	2024	128,977	167	141	76	(66)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Carrollton's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	9.00	0	0	0
1	2015	128,353	9.00	0	(47)	(47)
2	2016	128,451	9.00	0	(47)	(47)
3	2017	128,549	9.00	0	(47)	(47)
4	2018	128,648	9.00	0	(47)	(47)
5-year Goal	2019	128,746	9.00	0	(47)	(47)
6	2020	128,844	9.00	0	(47)	(47)
7	2021	128,877	9.00	0	(47)	(47)
8	2022	128,910	9.00	0	(47)	(47)
9	2023	128,944	9.00	0	(47)	(47)
10-year Goal	2024	128,977	9.00	0	(47)	(47)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Loss of 47 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
    a. Last rate increases:[17]
        i. 4.0% increase in 2016
        ii. 4.0% increase in 2017
    b. Estimated customer demand reduction of 1.6%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999) Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Outdoor Watering Ordinances	Conservation Pricing/Rate Increases	Irrigation System Permits	Stormwater Landscape Ordinance (ICI)	WaterWise Take-home Kits	Water Waste Violations + Inspections	Rainwater Harvesting	TOTAL SAVINGS
2010	Variable	1,122	54	6	0	26	23.5	1,231
2011	Variable	1,144	72	6	0.2	94	26.1	1,342
2012	3,316	1,167	90	6	0.4	135	26.5	4,741

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
  - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance

a. Potentially 8% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)

i. Average Region C savings

ii. Specific percentage of outdoor usage unknown for your utility at this time

b. Savings could be 615 MG per year with current demand.

c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	62	(47)	15	615	57	21	78	551
2017	123	(47)	76	615	57	26	83	608
2018	123	(47)	76	615	68	30	98	592
2019	123	(47)	76	615	80	34	114	576
2020	123	(47)	76	614	103	38	141	549
2021	123	(47)	76	614	109	38	147	543
2022	123	(47)	76	614	115	38	154	536
2023	123	(47)	76	614	122	38	160	529
2024	123	(47)	76	614	128	38	167	523
2025	123	(47)	76	614	134	38	173	516
2026	123	(47)	76	613	141	38	179	510
2027	123	(47)	76	613	147	38	186	503
2028	123	(47)	75	613	153	38	192	497
2029	123	(47)	75	613	160	38	198	490
2030	123	(47)	75	613	166	38	205	484
2031	122	(47)	75	612	172	35	207	480
2032	122	(47)	75	611	178	31	209	477
2033	122	(47)	75	610	184	27	211	474
2034	122	(47)	75	609	190	23	213	470
2035	122	(47)	74	608	196	19	215	467
2036	121	(47)	74	607	202	15	217	463
2037	121	(47)	74	606	208	12	219	460
2038	121	(47)	74	605	214	8	222	457
2039	121	(47)	74	604	220	4	224	453
2040	121	(47)	73	603	226	0	226	450

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[19]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	62	(47)	15	103	57	21	78	39
2017	123	(47)	76	103	57	26	83	96
2018	123	(47)	76	103	68	30	98	81
2019	123	(47)	76	103	80	34	114	65

2023	123	(47)	76	103	122	38	160	18
2024	123	(47)	76	103	128	38	167	12
2025	123	(47)	76	103	134	38	173	6
2026	123	(47)	76	103	141	38	179	(1)
2027	123	(47)	76	103	147	38	186	(7)
2028	123	(47)	75	103	153	38	192	(14)
2029	123	(47)	75	103	160	38	198	(20)
2030	123	(47)	75	103	166	38	205	(27)
2031	122	(47)	75	102	172	35	207	(29)
2032	122	(47)	75	102	178	31	209	(32)
2033	122	(47)	75	102	184	27	211	(34)
2034	122	(47)	75	102	190	23	213	(37)
2035	122	(47)	74	102	196	19	215	(39)
2036	121	(47)	74	102	202	15	217	(42)
2037	121	(47)	74	101	208	12	219	(44)
2038	121	(47)	74	101	214	8	222	(47)
2039	121	(47)	74	101	220	4	224	(49)
2040	121	(47)	73	101	226	0	226	(52)

3. Rain Barrels

  a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).

  b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of Cedar Hill Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Cedar Hill's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Cedar Hill's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Cedar Hill's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

---

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Cedar Hill with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	115	496	611	24	8	31	579
2016	118	505	623	29	10	39	584
2017	120	515	635	29	12	41	594
2018	123	525	647	35	13	49	598
2019	125	534	659	41	15	57	603
2020	128	544	672	53	17	70	601

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Cedar Hill's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	177	0	0	0
1	2015	48,507	176	25	611	586
2	2016	49,446	174	51	623	572
3	2017	50,384	173	77	635	558
4	2018	51,323	171	105	647	542
5-year Goal	2019	52,261	170	134	659	526
6	2020	53,200	170	144	672	528
7	2021	54,392	169	155	686	531
8	2022	55,584	169	166	701	535
9	2023	56,776	168	178	716	538
10-year Goal	2024	57,968	168	190	731	540

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Cedar Hill's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	42.00	0	0	0
1	2015	48,507	40.00	35	496	460
2	2016	49,446	38.00	72	505	433
3	2017	50,384	36.00	110	515	405
4	2018	51,323	34.00	150	525	375
5-year Goal	2019	52,261	32.00	191	534	343
6	2020	53,200	30.60	221	544	322
7	2021	54,392	29.20	254	556	302
8	2022	55,584	27.80	288	568	280
9	2023	56,776	26.40	323	580	257
10-year Goal	2024	57,968	25.00	360	592	233

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Savings of 496 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increase**
    a. Last rate increase:[17]
        i. 11.0% increase in 2013
    b. Estimated customer demand reduction of 2.2%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Advanced Metering Infrastructure (AMI) with Customer Engagement Portal**
    a. Implemented in 2013
    b. Estimated savings of 47.2 MG in 2016
        i. Specific utility results may vary based on portal features and notifications
    c. Assumes 20% of residential customers are using and saving water due to the portal (Westin Engineering, 2015)
    d. Assumes customers save 10% of total annual use due to the portal

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.

[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.

[17] Correspondence with utility staff.

[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

        i. Savings estimate is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
    e. Residential customers' use makes up approximately 74% of all retail customers' use based on utility profile information submitted to the TWDB
    f. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.48% of total demand
    g. Savings are assumed to increase along with demand as connections increase each year[19]
    h. Savings estimate may vary with specific features of FATHOM U2You portal

6. Rain Barrels

    a. In Region C, estimated savings of 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
        i. Estimated 10-year useful life for most barrels

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Rain Barrels	AMI with Customer Portal	Water Rate Increase	TOTAL SAVINGS
2012				0
2013		44.1	66	110
2014		45.1	67	112
2015		46.2	69	115
2016	0.1	47.2	70	118
2017	0.1	48.3	72	120
2018	0.1	49.3	73	123
2019	0.1	50.3	75	125
2020	0.1	51.4	76	128

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
   a. Potentially 8% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
      i. Average Region C savings
      ii. Specific percentage of outdoor usage unknown for your utility at this time
   b. Savings could be 255 MG per year with current demand.
   c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	118	505	623	255	29	10	39	839
2017	120	515	635	261	29	12	41	855
2018	123	525	647	266	35	13	49	865
2019	125	534	659	272	41	15	57	875
2020	128	544	672	278	53	17	70	879
2021	130	556	686	283	58	17	75	894
2022	133	568	701	289	63	17	81	909
2023	136	580	716	295	69	17	86	925

Statewide Water Conservation Quantification Project
City of Cockrell Hill Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Cockrell Hill's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Cockrell Hill's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Cockrell Hill's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD [7] consumption and water loss GPCD.[8] [9]

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.
[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365
[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.
[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Cockrell Hill with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	0	1.70	2	0	0	0	1
2016	8.6	1.73	10	0	0	1	10
2017	8.6	1.75	10	0	0	1	10
2018	8.6	1.78	10	0	1	1	10

2067	8.6	4.60	13	6	0	6	7
2068	8.6	4.89	13	7	0	7	7
2069	8.6	5.18	14	7	0	7	7
2070	8.6	5.48	14	7	0	7	7

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Cockrell Hill's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	100	0	0	0
1	2015	4,670	100	0	2	2
2	2016	4,738	100	0	10	10
3	2017	4,805	100	0	10	10
4	2018	4,873	100	0	10	10
5-year Goal	2019	4,940	100	0	10	10
6	2020	5,008	100	0	10	10
7	2021	5,019	100	0	10	10
8	2022	5,031	100	0	10	10
9	2023	5,042	100	0	10	10
10-year Goal	2024	5,054	100	0	10	10

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Cockrell Hill's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	19.00	0	0	0
1	2015	4,670	18.46	1	2	1
2	2016	4,738	17.92	2	2	(0)
3	2017	4,805	17.38	3	2	(1)
4	2018	4,873	16.84	4	2	(2)
5-year Goal	2019	4,940	16.30	5	2	(3)
6	2020	5,008	16.00	5	2	(4)
7	2021	5,019	15.70	6	2	(4)
8	2022	5,031	15.40	7	2	(5)
9	2023	5,042	15.10	7	2	(5)
10-year Goal	2024	5,054	14.80	8	2	(6)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Savings of 1.7 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Save Water Co. Commercial, Multi-family and Hotel Programs**[17]
    a. Project initiated in service area in 2016
    b. Save Water completed work on 116 multi-family units in 2016
    c. Average monthly savings of 713,185 gallons
    d. Annualized savings of 8.6 MG for the life of the retrofitted fixtures
    e. This study estimates a lifespan of 25 years for high-efficiency toilet replacements, five years for kitchen aerators and similar devices.
    f. Save Water Co. performs monthly meter readings before and after installation to quantify savings.
    g. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets and replacing sink aerators.

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Savings figures and units serviced based on personal email communication with Kurt Goedrich, December 1, 2016.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Save Water Co. Program	TOTAL SAVINGS
2009		0
2010		0
2011		0
2012		0
2013		0
2014		0
2015		0
2016	9	8.6
2017	9	8.6
2018	9	8.6
2019	9	8.6
2020	9	8.6

2020	5,008	18.00	2
2021	5,019	18.00	2
2022	5,031	18.00	2
2023	5,042	18.00	2
2024	5,054	18.00	2

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - o The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs
    - o Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
    a. Potentially 8% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
        i. Average Region C savings
        ii. Specific percentage of outdoor usage unknown for your utility at this time
    b. Savings could be 10 MG per year with current demand.
    c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	9	2	10	10	0	0	1	20
2017	9	2	10	11	0	0	1	20
2018	9	2	10	11	0	1	1	20
2019	9	2	10	11	0	1	1	20
2020	9	2	10	11	0	1	1	20
2021	9	2	10	11	0	1	1	20
2022	9	2	10	11	0	1	1	20
2023	9	2	10	11	1	1	1	20
2024	9	2	10	11	1	1	1	20
2025	9	2	10	11	1	1	1	20
2026	9	2	10	11	1	1	1	20
2027	9	2	10	11	1	1	1	20
2028	9	2	10	11	1	1	1	20
2029	9	2	10	11	1	1	2	20
2030	9	2	10	11	1	1	2	20
2031	9	2	10	11	1	1	2	20
2032	9	2	10	11	1	1	2	20
2033	9	2	10	11	1	0	2	20
2034	9	2	10	11	1	0	1	20
2035	9	2	10	11	1	0	1	20
2036	9	2	10	11	1	0	1	20
2037	9	2	10	11	1	0	1	20
2038	9	2	10	11	1	0	1	20
2039	9	2	10	11	1	0	1	20
2040	9	2	10	11	1	0	1	20

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[18]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

[18] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	9	2	10	2	0	0	1	11
2017	9	2	10	2	0	0	1	11
2018	9	2	10	2	0	1	1	11
2019	9	2	10	2	0	1	1	11

2034	9	2	10	2	1	0	1	11
2035	9	2	10	2	1	0	1	11
2036	9	2	10	2	1	0	1	11
2037	9	2	10	2	1	0	1	11
2038	9	2	10	2	1	0	1	11
2039	9	2	10	2	1	0	1	11
2040	9	2	10	2	1	0	1	11

3. Water Rate Increase

- **a.** For every 10% increase, estimated savings could be 2% of utility total demand.
- **b.** Approximately 3 MG of savings per year with current demand
- **c.** Savings is cumulative and based on more than one source[19] (U.S. EPA, 1998; Whitcomb, 1999)
- **d.** See Table 6-3 for potential savings from this measure compared with the utility's conservation goals.

Table 6-3. Current Savings + Potential Savings from 10% Water Rate Increase (MG).

[19] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Water Rate Increase	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	9	2	10	3	0	0	1	12
2017	9	2	10	3	0	0	1	12
2018	9	2	10	3	0	1	1	12
2019	9	2	10	3	0	1	1	12
2020	9	2	10	3	0	1	1	12
2021	9	2	10	3	0	1	1	12

2039	9	2	10	3	1	0	1	12
2040	9	2	10	3	1	0	1	12

4. Rain Barrels

a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).

b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of Colleyville Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Colleyville's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Colleyville's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Colleyville's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.
[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.
[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365
[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.
[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Colleyville with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	62	65	127	18	7	25	102
2016	62	64	127	22	9	31	96

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Colleyville's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	299	0	0	0
1	2015	25,487	296	28	127	99
2	2016	25,190	293	55	127	72
3	2017	24,892	290	82	126	45
4	2018	24,595	287	108	126	18
5-year Goal	2019	24,297	284	133	126	(7)
6	2020	24,000	281	156	125	(31)
7	2021	24,150	278	182	126	(56)
8	2022	24,300	276	208	127	(81)
9	2023	24,450	273	234	127	(107)
10-year Goal	2024	24,600	270	260	128	(132)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Colleyville's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	14.00	0	0	0
1	2015	25,487	14.00	0	65	65
2	2016	25,190	14.00	0	64	64
3	2017	24,892	14.00	0	64	64
4	2018	24,595	14.00	0	63	63
5-year Goal	2019	24,297	14.00	0	62	62
6	2020	24,000	14.00	0	61	61
7	2021	24,150	14.00	0	62	62
8	2022	24,300	14.00	0	62	62
9	2023	24,450	14.00	0	62	62
10-year Goal	2024	24,600	14.00	0	63	63

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Savings of 65 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
    a. Last rate increases:[17]
        i. 4.0% increase in 2014
        ii. 6.5% increase in 20
    b. Estimated customer demand reduction of 2.1%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Water Rate Increases	TOTAL SAVINGS
2009		0
2010		0
2011		0
2012		0
2013		0
2014	23.5	24
2015	62.1	62
2016	62.4	62
2017	62.8	63
2018	63.1	63

2024	24,600	7.00	63

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs

  - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs
  - Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
   a. Potentially 8% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
      i. Average Region C savings
      ii. Specific percentage of outdoor usage unknown for your utility at this time
   b. Savings could be 62 MG per year with current demand.
   c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	62	64	127	62	22	9	31	158
2017	63	64	126	63	22	10	33	157
2018	63	63	126	63	27	12	39	150
2019	63	62	126	63	31	14	45	144
2020	64	61	125	64	40	15	56	133
2021	64	62	126	64	43	15	59	131
2022	64	62	127	64	46	15	61	130
2023	65	62	127	65	49	15	64	128
2024	65	63	128	65	52	15	67	126
2025	65	63	129	65	55	15	70	124
2026	66	64	129	66	58	15	73	122
2027	66	64	130	66	60	15	76	120
2028	66	64	131	66	63	15	79	119
2029	67	65	132	67	66	15	82	117
2030	67	65	132	67	69	15	84	115
2031	67	66	133	67	72	14	86	114
2032	68	66	134	68	75	12	88	114
2033	68	66	134	68	79	11	89	113
2034	69	67	135	69	82	9	91	113
2035	69	67	136	69	85	8	93	112
2036	69	67	137	69	88	6	94	112
2037	70	68	137	70	91	5	96	111
2038	70	68	138	70	94	3	97	111
2039	70	69	139	70	98	2	99	110
2040	71	69	140	71	101	0	101	109

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[19]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	62	64	127	40	22	9	31	136
2017	63	64	126	40	22	10	33	134

3. Rain Barrels
   a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
   b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
Copeville SUD Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Copeville SUD's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Copeville SUD's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Copeville SUD's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD [7] consumption and water loss GPCD.[8] [9]

---

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Copeville SUD with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	0	(2.0)	(2.0)	0.1	0.3	0.4	(2.4)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Copeville SUD's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	75	0	0	0
1	2016	3,809	75	0.5	0	(0.5)
2	2017	3,818	74	1.1	2.0	0.9
3	2018	3,828	74	1.6	2.0	0.4
4	2019	3,837	73	2.1	2.1	(0.0)
5-year Goal	2020	3,846	73	2.7	2.1	(0.5)
6	2021	3,942	73	3.3	2.2	(1.1)
7	2022	4,038	72	4.0	2.3	(1.7)
8	2023	4,133	72	4.7	2.4	(2.3)
9	2024	4,229	71	5.4	2.4	(3.0)
10-year Goal	2025	4,325	71	6.1	2.4	(3.7)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Copeville SUD's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	7.54	0	0	0
1	2016	3,809	7.48	0.1	(2.0)	(2.1)
2	2017	3,818	7.42	0.2	(2.0)	(2.2)
3	2018	3,828	7.37	0.2	(2.0)	(2.3)
4	2019	3,837	7.31	0.3	(2.0)	(2.4)
5-year Goal	2020	3,846	7.25	0.4	(2.0)	(2.4)
6	2021	3,942	7.20	0.5	(2.0)	(2.5)
7	2022	4,038	7.15	0.6	(2.0)	(2.6)
8	2023	4,133	7.10	0.7	(2.0)	(2.7)
9	2024	4,229	7.05	0.8	(2.1)	(2.9)
10-year Goal	2025	4,325	7.00	0.9	(2.2)	(3.0)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Loss of 2 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
    a. Last rate increases:[17]
        i. 10.1% increase in 2016
        ii. 10.0% increase in 2017
    b. Estimated customer demand reduction of 4.0%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
    a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
    b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
    i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

5 Summary of Savings

2024	3,942	9.00	(2.1)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
   a. Potentially 8% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
      i. Average Region C savings
      ii. Specific percentage of outdoor usage unknown for your utility at this time
   b. Savings could be 8 MG per year with current demand.
   c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	2	(2)	(0)	8	0	0	1	7
2017	4	(2)	2	8	0	0	1	9
2018	4	(2)	2	8	0	1	1	9
2019	4	(2)	2	8	0	1	1	9
2020	4	(2)	2	8	0	1	1	9
2021	4	(2)	2	8	0	1	1	10
2022	4	(2)	2	9	0	1	1	10
2023	4	(2)	2	9	1	1	1	10
2024	4	(2)	2	9	1	1	1	10
2025	5	(2)	2	9	1	1	1	10
2026	5	(2)	2	9	1	1	1	10
2027	5	(2)	2	9	1	1	1	10
2028	5	(2)	2	10	1	1	1	10
2029	5	(2)	2	10	1	1	2	11
2030	5	(2)	3	10	1	1	2	11
2031	5	(2)	3	10	1	1	2	11
2032	5	(3)	3	10	1	1	2	11
2033	5	(3)	3	10	1	0	2	11
2034	5	(3)	3	11	1	0	2	12
2035	5	(3)	3	11	1	0	2	12
2036	6	(3)	3	11	1	0	2	12
2037	6	(3)	3	11	1	0	2	12
2038	6	(3)	3	11	1	0	2	13
2039	6	(3)	3	12	2	0	2	13
2040	6	(3)	3	12	2	0	2	13

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[19]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	2	(2)	(0)	1	0	0	1	1
2017	4	(2)	2	1	0	0	1	3
2018	4	(2)	2	1	0	1	1	3
2019	4	(2)	2	1	0	1	1	3
2020	4	(2)	2	1	0	1	1	3
2021	4	(2)	2	1	0	1	1	3
2022	4	(2)	2	1	0	1	1	3
2023	4	(2)	2	1	1	1	1	3
2024	4	(2)	2	1	1	1	1	3
2025	5	(2)	2	2	1	1	1	3
2026	5	(2)	2	2	1	1	1	3
2027	5	(2)	2	2	1	1	1	3
2028	5	(2)	2	2	1	1	1	3
2029	5	(2)	2	2	1	1	2	3
2030	5	(2)	3	2	1	1	2	3
2031	5	(2)	3	2	1	1	2	3
2032	5	(3)	3	2	1	1	2	3
2033	5	(3)	3	2	1	0	2	3
2034	5	(3)	3	2	1	0	2	3
2035	5	(3)	3	2	1	0	2	3
2036	6	(3)	3	2	1	0	2	3
2037	6	(3)	3	2	1	0	2	3
2038	6	(3)	3	2	1	0	2	3
2039	6	(3)	3	2	2	0	2	3
2040	6	(3)	3	2	2	0	2	3

3. Rain Barrels
    a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
    b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of Coppell Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Coppell's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Coppell's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Coppell's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Coppell with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	106	(90)	16	21	8	29	(13)
2016	106	(90)	16	26	10	36	(20)
2017	199	(90)	109	26	12	38	71

2068	202	(94)	108	142	0	142	(34)
2069	202	(94)	108	143	0	143	(35)
2070	202	(94)	108	144	0	144	(36)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Coppell's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	251	0	0	0
1	2016	41,219	243	117	16	(101)
2	2017	41,279	235	235	16	(219)
3	2018	41,340	228	353	109	(244)
4	2019	41,400	220	471	109	(362)
5-year Goal	2020	41,460	212	590	109	(481)
6	2021	41,609	212	598	110	(489)
7	2022	41,759	211	607	110	(497)
8	2023	41,908	211	615	110	(505)
9	2024	42,057	210	623	110	(513)
10-year Goal	2025	42,207	210	632	110	(521)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Coppell's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	13.00	0	0	0
1	2016	41,219	13.00	0	(90)	(90)
2	2017	41,279	13.00	0	(90)	(90)
3	2018	41,340	13.00	0	(91)	(91)
4	2019	41,400	13.00	0	(91)	(91)
5-year Goal	2020	41,460	13.00	0	(91)	(91)
6	2021	41,609	13.00	0	(91)	(91)
7	2022	41,759	13.00	0	(91)	(91)
8	2023	41,908	13.00	0	(92)	(92)
9	2024	42,057	13.00	0	(92)	(92)
10-year Goal	2025	42,207	13.00	0	(92)	(92)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Loss of 90 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
    a. Last rate increases:[17]
        i. 15% increase in 2015
        ii. 13% increase in 2017
    b. Estimated customer demand reduction of 5.6%
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
    a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
    b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
    i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Water Rate Increase	TOTAL SAVINGS
2012		0
2013		0
2014		0
2015	106.2	106
2016	106.5	106
2017	199.2	199
2018	199.7	200
2019	200.1	200
2020	200.6	201

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	13.00	0
2015	41,159	19.00	(90)
2016	41,219	19.00	(90)
2017	41,279	19.00	(90)
2018	41,340	19.00	(91)
2019	41,400	19.00	(91)
2020	41,460	19.00	(91)
2021	41,609	19.00	(91)
2022	41,759	19.00	(91)
2023	41,908	19.00	(92)
2024	42,057	19.00	(92)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
  - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
    a. Potentially 8% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
        i. Average Region C savings
        ii. Specific percentage of outdoor usage unknown for your utility at this time
    b. Savings could be 284 MG per year with current demand.
    c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	106	(90)	16	284	26	10	36	264
2017	199	(90)	109	285	26	12	38	355
2018	200	(91)	109	285	31	14	45	349
2019	200	(91)	109	286	37	16	52	343
2020	201	(91)	110	287	47	18	65	331
2021	201	(91)	110	287	50	18	68	329

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[19]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[19] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

2040	203	(94)	109	49	109	0	109	49

3. Rain Barrels
    a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
    b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of Corinth Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

> after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Corinth's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Corinth's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Corinth's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Corinth with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	0.3	(38)	(38)	8	3	11	(49)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Corinth's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	149	0	0	0
1	2017	22,563	147	15	(41)	(56)
2	2018	23,346	145	31	(42)	(73)
3	2019	24,128	144	48	(44)	(91)
4	2020	24,911	142	65	(45)	(111)
5-year Goal	2021	25,370	140	83	(46)	(130)
6	2022	25,829	139	96	(47)	(143)
7	2023	26,287	138	109	(48)	(157)
8	2024	26,746	136	123	(49)	(172)
9	2025	27,205	135	137	(50)	(187)
10-year Goal	2026	27,664	134	151	(50)	(202)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Corinth's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	9.00	0	0	0
1	2017	22,563	8.60	3	(41)	(44)
2	2018	23,346	8.20	7	(43)	(49)
3	2019	24,128	7.80	11	(44)	(55)
4	2020	24,911	7.40	15	(45)	(60)
5-year Goal	2021	25,370	7.00	19	(46)	(65)
6	2022	25,829	6.60	23	(47)	(70)
7	2023	26,287	6.20	27	(48)	(75)
8	2024	26,746	5.80	31	(49)	(80)
9	2025	27,205	5.40	36	(50)	(85)
10-year Goal	2026	27,664	5.00	40	(50)	(91)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
   a. Easy-to-use website with conservation tips and water rates
   b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
   a. The utility engages the public in many ways including:
      i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
   a. Loss of 38 MG annually in 2015
   b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
   c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
   d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
   a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
   b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.
   c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
      i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

5. **Outdoor landscape evaluations for single family (SF) customers**
   a. 96 outdoor evaluations performed or projected to perform since 2016
   b. Estimated 8,000 gallons per year for each system evaluation (A&N Technical Services, 2005)
      i. Assumed 65% savings from typical indoor and outdoor survey when only outdoor watering is evaluated (Whitcomb, 2000)
   c. Approximately 22 gallons per day

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.

d. Greater savings during peak periods
e. Lesser savings during off-peak periods
b. 20% decay rate per year attributed to customer behavior (A&N Technical Services, 2005)

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Outdoor Water Audits	TOTAL SAVINGS
2012	0.1	0.1
2013	0.2	0.2
2014	0.2	0.2

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	9.00	0
2015	20,998	14.00	(38)
2016	21,781	14.00	(40)
2017	22,563	14.00	(41)
2018	23,346	14.00	(43)
2019	24,128	14.00	(44)
2020	24,911	14.00	(45)
2021	25,370	14.00	(46)
2022	25,829	14.00	(47)
2023	26,287	14.00	(48)
2024	26,746	14.00	(49)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
  - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
   a. Potentially 9.89% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
   b. Savings could be 128 MG per year with current demand.
   c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	0	(40)	(39)	128	10	4	14	75
2017	0	(41)	(41)	131	10	5	15	75
2018	0	(43)	(42)	133	12	5	18	73
2019	0	(44)	(44)	135	14	6	21	71
2020	0	(45)	(45)	137	19	7	25	67
2021	0	(46)	(46)	140	20	7	27	67
2022	0	(47)	(47)	142	22	7	29	66
2023	0	(48)	(48)	144	24	7	30	66
2024	0	(49)	(49)	147	25	7	32	66
2025	0	(50)	(50)	149	27	7	34	66
2026	0	(50)	(50)	151	29	7	35	65
2027	0	(51)	(51)	154	30	7	37	65
2028	0	(52)	(52)	156	32	7	39	65
2029	0	(53)	(53)	158	34	7	40	65
2030	0	(54)	(54)	161	35	7	42	65
2031	0	(54)	(54)	161	37	6	43	64
2032	0	(54)	(54)	160	38	5	43	63
2033	0	(54)	(54)	160	39	5	44	63
2034	0	(54)	(54)	160	41	4	45	62
2035	0	(54)	(54)	160	42	3	45	61
2036	0	(54)	(54)	160	43	3	46	60
2037	0	(54)	(54)	160	45	2	47	60
2038	0	(54)	(54)	160	46	1	47	59
2039	0	(54)	(54)	160	47	1	48	58
2040	0	(54)	(54)	160	49	0	49	57

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[17]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[17] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	0	(40)	(39)	17	10	4	14	(36)
2017	0	(41)	(41)	18	10	5	15	(38)
2018	0	(43)	(42)	18	12	5	18	(42)
2019	0	(44)	(44)	18	14	6	21	(46)
2020	0	(45)	(45)	19	19	7	25	(52)
2021	0	(46)	(46)	19	20	7	27	(54)
2022	0	(47)	(47)	19	22	7	29	(57)
2023	0	(48)	(48)	20	24	7	30	(59)
2024	0	(49)	(49)	20	25	7	32	(61)
2025	0	(50)	(50)	20	27	7	34	(63)
2026	0	(50)	(50)	21	29	7	35	(65)
2027	0	(51)	(51)	21	30	7	37	(68)
2028	0	(52)	(52)	21	32	7	39	(70)
2029	0	(53)	(53)	21	34	7	40	(72)
2030	0	(54)	(54)	22	35	7	42	(74)
2031	0	(54)	(54)	22	37	6	43	(75)
2032	0	(54)	(54)	22	38	5	43	(75)
2033	0	(54)	(54)	22	39	5	44	(76)
2034	0	(54)	(54)	22	41	4	45	(77)
2035	0	(54)	(54)	22	42	3	45	(77)
2036	0	(54)	(54)	22	43	3	46	(78)
2037	0	(54)	(54)	22	45	2	47	(79)
2038	0	(54)	(54)	22	46	1	47	(79)
2039	0	(54)	(54)	22	47	1	48	(80)
2040	0	(54)	(54)	22	49	0	49	(81)

3. Water Rate Increase
   a. For every 10% increase, estimated savings could be 2% of utility total demand.
   b. Approximately 26 MG of savings per year with current demand
   c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
   d. See Table 6-3 for potential savings from this measure compared with the utility's conservation goals.

[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

Table 6-3. Current Savings + Potential Savings from 10% Water Rate Increase (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Water Rate Increase	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	0	(40)	(39)	26	10	4	14	(28)
2017	0	(41)	(41)	26	10	5	15	(29)
2018	0	(43)	(42)	27	12	5	18	(33)
2019	0	(44)	(44)	27	14	6	21	(37)
2020	0	(45)	(45)	28	19	7	25	(43)
2021	0	(46)	(46)	28	20	7	27	(45)
2022	0	(47)	(47)	29	22	7	29	(47)
2023	0	(48)	(48)	29	24	7	30	(49)
2024	0	(49)	(49)	30	25	7	32	(51)
2025	0	(50)	(50)	30	27	7	34	(53)
2026	0	(50)	(50)	31	29	7	35	(55)
2027	0	(51)	(51)	31	30	7	37	(57)
2028	0	(52)	(52)	32	32	7	39	(59)
2029	0	(53)	(53)	32	34	7	40	(61)
2030	0	(54)	(54)	32	35	7	42	(63)
2031	0	(54)	(54)	32	37	6	43	(64)
2032	0	(54)	(54)	32	38	5	43	(65)
2033	0	(54)	(54)	32	39	5	44	(65)
2034	0	(54)	(54)	32	41	4	45	(66)
2035	0	(54)	(54)	32	42	3	45	(67)
2036	0	(54)	(54)	32	43	3	46	(67)
2037	0	(54)	(54)	32	45	2	47	(68)
2038	0	(54)	(54)	32	46	1	47	(69)
2039	0	(54)	(54)	32	47	1	48	(69)
2040	0	(54)	(54)	32	49	0	49	(70)

4. Rain Barrels
    a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
    b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of Corsicana Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Corsicana's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Corsicana's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Corsicana's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

---

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Corsicana with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-1.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	0	44	44	12	4	16	28
2016	0	45	45	14	5	20	25

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Corsicana's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	151	0	0	0
1	2015	23,989	152	(5)	44	49
2	2016	24,451	152	(11)	45	55
3	2017	24,913	153	(16)	45	62
4	2018	25,374	153	(22)	46	69
5-year Goal	2019	25,836	154	(28)	47	75
6	2020	26,298	153	(15)	48	63
7	2021	26,568	151	(2)	48	50
8	2022	26,838	150	12	49	37
9	2023	27,108	148	26	49	24
10-year Goal	2024	27,378	147	40	50	10

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Corsicana's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-1 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	31.00	0	0	0
1	2015	23,989	27.60	30	44	14
2	2016	24,451	24.20	61	45	(16)
3	2017	24,913	20.80	93	45	(47)
4	2018	25,374	17.40	126	46	(80)
5-year Goal	2019	25,836	14.00	160	47	(113)
6	2020	26,298	13.20	171	48	(123)
7	2021	26,568	12.40	180	48	(132)
8	2022	26,838	11.60	190	49	(141)
9	2023	27,108	10.80	200	49	(150)
10-year Goal	2024	27,378	10.00	210	50	(160)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
   a. Easy-to-use website with conservation tips and water rates
   b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
   a. The utility engages the public in many ways including:
      i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
   a. Savings of 44 MG annually in 2015
   b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
   c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
   d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.

5 Summary of Savings

Table 5-1. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	31.00	0
2015	23,989	26.00	44
2016	24,451	26.00	45
2017	24,913	26.00	45
2018	25,374	26.00	46
2019	25,836	26.00	47
2020	26,298	26.00	48
2021	26,568	26.00	48
2022	26,838	26.00	49
2023	27,108	26.00	49
2024	27,378	26.00	50

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.

- Avoided system expansion costs
    - Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
   a. Potentially 9.05% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
   b. Savings could be 171 MG per year with current demand.
   c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	0	45	45	171	14	5	20	196
2017	0	45	45	173	14	7	21	197
2018	0	46	46	174	17	8	25	196
2019	0	47	47	176	20	9	29	194

2035	0	55	55	198	57	5	62	192
2036	0	56	56	200	59	4	63	193
2037	0	56	56	201	62	3	65	193
2038	0	57	57	203	64	2	66	194
2039	0	57	57	204	66	1	67	195
2040	0	58	58	206	68	0	68	196

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

   a. Specific utility results will vary based on portal features and frequency of customer notifications
   b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
   c. Estimate assumes customers will save 10% of total annual use due to the portal

i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)

d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB

i. This was the most common percentage of residential use among participating utilities in this project.

ii. Actual customer class demand percentages will vary by utility.

e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand

f. Savings are assumed to increase along with demand as connections increase each year[17]

g. See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	0	45	45	25	14	5	20	50
2017	0	45	45	26	14	7	21	50
2018	0	46	46	26	17	8	25	47

2029	0	52	52	28	44	10	53	27
2030	0	53	53	28	46	10	55	26
2031	0	53	53	28	48	9	57	25
2032	0	54	54	29	50	8	58	25
2033	0	54	54	29	52	7	59	24
2034	0	55	55	29	55	6	61	24
2035	0	55	55	29	57	5	62	23
2036	0	56	56	30	59	4	63	22
2037	0	56	56	30	62	3	65	22
2038	0	57	57	30	64	2	66	21
2039	0	57	57	30	66	1	67	21
2040	0	58	58	30	68	0	68	20

[17] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

3. Water Rate Increase
    a. For every 10% increase, estimated savings could be 2% of utility total demand.
    b. Approximately 38 MG of savings per year with current demand
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. See Table 6-3 for potential savings from this measure compared with the utility's conservation goals.

Table 6-3. Current Savings + Potential Savings from 10% Water Rate Increase (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Water Rate Increase	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

2035	0	55	55	44	57	5	62	37
2036	0	56	56	44	59	4	63	37
2037	0	56	56	45	62	3	65	36
2038	0	57	57	45	64	2	66	36
2039	0	57	57	45	66	1	67	36
2040	0	58	58	46	68	0	68	35

4. Rain Barrel
    a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
    b. Estimated 10-year useful life for most barrels

[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

Statewide Water Conservation Quantification Project
City of Crowley Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Crowley's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Crowley's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Crowley's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Crowley with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

<u>Actual Current Conservation Activity Savings</u> – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	59	(36)	23	1	2	3	20
2016	60	(37)	23	1	2	4	20

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Crowley's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	126	0	0	0
1	2016	15,155	121	29	23	(6)
2	2017	15,457	116	59	23	(35)
3	2018	15,758	110	90	23	(66)
4	2019	16,060	105	122	24	(98)
5-year Goal	2020	16,362	100	155	24	(131)
6	2021	16,640	98	173	24	(149)
7	2022	16,918	95	191	24	(167)
8	2023	17,196	93	210	25	(186)
9	2024	17,474	90	230	25	(205)
10-year Goal	2025	17,752	88	249	25	(224)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Crowley's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	Baseline	-	8.00	0	0	0
1	2016	15,155	7.40	3	(37)	(40)
2	2017	15,457	6.80	7	(37)	(44)
3	2018	15,758	6.20	10	(38)	(48)
4	2019	16,060	5.60	14	(39)	(53)
5-year Goal	2020	16,362	5.00	18	(39)	(57)
6	2021	16,640	4.80	19	(40)	(60)
7	2022	16,918	4.60	21	(41)	(62)
8	2023	17,196	4.40	23	(41)	(64)
9	2024	17,474	4.20	24	(42)	(66)
10-year Goal	2025	17,752	4.00	26	(43)	(69)

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, we used a 50/50 savings split when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
   a. Easy-to-use website with conservation tips and water rates
   b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
   a. The utility engages the public in many ways including:
      i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
   a. Loss of 36 MG annually in 2015
   b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
   c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
   d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
   a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
   b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.
   c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
      i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

5. **Twice-a-week Outdoor Watering Restriction Ordinance**
   a. Estimated savings of 8.0% of total utility demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and the National Wildlife Federation, 2015)
   b. All savings estimates grow each year at the same rate demand figures for the utility grow in the regional water plan.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	2x Watering Ordinance	TOTAL SAVINGS
2012		0
2013		0
2014	57.8	58
2015	58.7	59
2016	59.6	60
2017	60.5	61
2018	61.5	61
2019	62.4	62
2020	63.3	63
2021	64.2	64
2022	65.1	65
2023	66.0	66
2024	66.9	67
2025	67.8	68
2026	68.7	69

2062	133.9	134
2063	135.7	136
2064	137.6	138
2065	139.4	139
2066	141.3	141
2067	143.1	143
2068	145.0	145
2069	146.8	147
2070	148.7	149

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	6.40	0
2015	14,853	13.00	(36)
2016	15,155	13.00	(37)
2017	15,457	13.00	(37)
2018	15,758	13.00	(38)
2019	16,060	13.00	(39)
2020	16,362	13.00	(39)
2021	16,640	13.00	(40)
2022	16,918	13.00	(41)
2023	17,196	13.00	(41)
2024	17,474	13.00	(42)

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- o Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications
b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
c. Estimate assumes customers will save 10% of total annual use due to the portal
    i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    i. This was the most common percentage of residential use among participating utilities in this project.
    ii. Actual customer class demand percentages will vary by utility.
e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
f. Savings are assumed to increase along with demand as connections increase each year[17]

[17] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

g. See Table 6-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	59	(37)	22	10	1	2	4	29
2017	60	(37)	22	10	1	3	4	28
2018	61	(38)	23	10	2	3	5	28
2019	61	(39)	23	10	2	3	6	28
2020	62	(39)	23	11	3	4	7	27

2025	67	(43)	24	11	4	4	8	27
2026	68	(43)	24	12	5	4	8	27
2027	69	(44)	25	12	5	4	9	27
2028	70	(45)	25	12	5	4	9	28
2029	71	(45)	25	12	6	4	9	28
2030	71	(46)	25	12	6	4	10	28
2031	72	(47)	25	12	6	4	10	28
2032	74	(48)	26	13	7	3	10	28
2033	75	(49)	26	13	7	3	10	29
2034	76	(50)	27	13	8	2	10	29
2035	78	(51)	27	13	8	2	10	30
2036	79	(52)	27	13	9	2	10	30
2037	80	(52)	28	14	9	1	10	31
2038	81	(53)	28	14	10	1	11	31
2039	83	(54)	29	14	10	0	11	32
2040	84	(55)	29	14	11	0	11	32

2. Water Rate Increase
    a. For every 10% increase, estimated savings could be 2% of utility total demand.
    b. Approximately 15 MG of savings per year with current demand
    c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
    d. See Table 6-2 for potential savings from this measure compared with the utility's conservation goals.

[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

Table 6-2. Current Savings + Potential Savings from 10% Water Rate Increase (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Water Rate Increase	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	59	(37)	22	15	1	2	4	34
2017	60	(37)	22	15	1	3	4	33
2018	61	(38)	23	15	2	3	5	33
2019	61	(39)	23	16	2	3	6	33

2030	71	(46)	25	18	6	4	10	34
2031	72	(47)	25	18	6	4	10	34
2032	74	(48)	26	19	7	3	10	35
2033	75	(49)	26	19	7	3	10	35
2034	76	(50)	27	19	8	2	10	36
2035	78	(51)	27	20	8	2	10	36
2036	79	(52)	27	20	9	2	10	37
2037	80	(52)	28	20	9	1	10	38
2038	81	(53)	28	21	10	1	11	38
2039	83	(54)	29	21	10	0	11	39
2040	84	(55)	29	21	11	0	11	39

3. Rain Barrels
   a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
   b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
DWU – City of Dallas Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal conservation terminology and review of methodology used by regional planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common

[1] Equal to 811,224 acre-feet per year in conservation savings.

association
- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional planning group approach to determining supply volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached, after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, as much relevant data as possible was collected from participant utilities. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Each utility's conservation activities were then quantified through several different means, including evidence-based studies, utility-provided results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.

assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Dallas's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Dallas's own five- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.

The five- and 10-year goals in Dallas's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[5] are expressed in decreasing total GPCD [6] consumption and water loss GPCD.[7] [8]

---

[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

[5] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[6] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[7] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[8] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

This report also contains additional tables not included in other individual reports that project Dallas's conservation activities according to feedback received from utility staff. To be consistent with the rest of the project, only utility savings for activities implemented through 2016 are included in Tables 3-1 through 3-3. For details on savings estimates from projected activities, see Sections 6 and 7 in this report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[9] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because we used a single year (2015) value for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures we have carried forward in our model because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. Our approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current savings compared to conservation WMS supply volume (in million gallons) in regional water plan

Table 3-1 shows the 2070 planning period for Dallas with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

---

[9] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, excluding savings from water loss reduction. Because the regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, we have quantified utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[10] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [11] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[11] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current savings compared to conservation WMS supply volume (MG) in regional water plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	8,301	0	8,301	1,367	199	1,567	6,734

3.2 Utility water conservation plan goals – total GPCD

Table 3-2 shows how Dallas's quantified savings from its implemented activities compare with five- and goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.[12]

Total GPCD Goals – Total GPCD goals start with the utility's baseline for total GPCD and progress in subsequent years to match five- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Section 6 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility water conservation plan goals — total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	204	0	0	0
1	2015	1,244,270	202	727	8,301	7,574
2	2016	1,257,730	201	1,469	10,579	9,110
3	2017	1,270,170	199	2,225	10,582	8,356
4	2018	1,283,120	198	2,997	10,606	7,608
5-year Goal	2019	1,296,070	196	3,785	10,641	6,857
6	2020	1,309,020	196	3,918	10,684	6,766
7	2021	1,321,970	196	4,053	10,733	6,680
8	2022	1,334,920	195	4,190	10,792	6,602
9	2023	1,347,870	195	4,329	10,740	6,411
10-year Goal	2024	1,360,820	195	4,470	10,687	6,216

[12] Population estimates through 2017 were gathered from North Central Texas Council of Governments public data. Estimates for years 2018 through 2024 were calculated by taking an average of growth rates from 2015 through 2017 (12,950 people per year).

3.3 Utility water conservation plan goals – water loss GPCD

Table 3-3 shows how Dallas's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated. [13]

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline for water loss GPCD and progress in subsequent years to match five- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility water conservation plan goals — water loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	29.00	0	0	0
1	2015	1,244,270	28.80	91	0	(91)
2	2016	1,257,730	28.60	184	0	(184)
3	2017	1,270,170	28.40	278	0	(278)
4	2018	1,283,120	28.20	375	0	(375)
5-year Goal	2019	1,296,070	28.00	473	0	(473)
6	2020	1,309,020	27.80	573	0	(573)
7	2021	1,321,970	27.60	676	0	(676)
8	2022	1,334,920	27.40	780	0	(780)
9	2023	1,347,870	27.20	886	0	(886)
10-year Goal	2024	1,360,820	27.00	993	0	(993)

[13] Population estimates through 2017 were gathered from North Central Texas Council of Governments public data. Estimates for years 2018 through 2024 were calculated by taking an average of growth rates from 2015 through 2017 (12,950 people per year).

4 Implemented activities through 2016

Below is a list of *completed* activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. For the year 2016, this report used an average savings estimate from previous years' savings results. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water rate increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). During the project, we were able to survey several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, we used a 50/50 savings split when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized activities

1. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
    a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
    b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.
    c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 8 of this report.
        i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

2. **Twice-per-week (or less) Outdoor Watering Ordinance**
    a. Estimated savings of 8.42% of total utility demand while ordinance in place (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
    b. All savings estimates grow each year at the same rate demand figures for the utility grow in the regional water plan.

3. **Water Rate Increases**
    a. Major rate increase from 2013 – 2016:[14]
        i. 11.125% combined base rate increase
        ii. 11.425% combined volumetric rate increase
        iii. 11.275% overall increase with 50/50 weight given to base and volumetric rate increases = 2.255% of total demand
    b. Savings are cumulative and based on TWDB's Best Management Practices for Municipal Water Users Guide[15] (Texas Water Development Board, 2013), as well as Environmental Protection Agency guidelines and other sources (U.S. EPA, 1998; Whitcomb, 1999)

4. **Free Irrigation Inspections (SF/MF/C)**
    a. More than 5,700 inspections since program inception
    b. Savings estimates per year since 2009 were provided by utility (City of Dallas Water Utilities, 2016)
    c. For 2016, assumed an average of 844 audits and annual savings of 61,966 gallons per year per audit based on past savings figures provided by utility (City of Dallas Water Utilities, 2016)
    d. 20% decay rate per year attributed to customer behavior for similar programs (A&N Technical Services, 2005)

---

[14] Gathered from rates listed in 2013 and in 2016 from documents collected from staff.

[15] Water Conservation Advisory Council (WCAC) estimates 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, we can determine the savings for lower or higher percentage increases.

5. **Free Water Efficiency Surveys (ICI)**
    a. More than 320 surveys conducted from 2013 – 2015 (City of Dallas Water Utilities, 2016)
    b. Estimated 107 surveys completed annually
    c. Estimated savings of 1.049 MG per year per audit
    d. Approximately 112.3 MG stand alone peak annual savings, which amounts to 337 accumulated savings across three years (2013 – 2015)
    e. Because some measures implemented during the surveys included equipment, fixtures, and other hardware, assumed a 10-year useful life for savings with no decay rate to be conservative
        i. Savings could persist longer for some hardware items, while behavioral measures could mean savings decay at a faster rate

6. **City-owned Facilities Retrofit**
    a. From 2010 – 2015, estimated accumulated savings of 2.56 MG annually (City of Dallas Water Utilities, 2016)
    b. Estimated average savings of 426,667 gallons per year
    c. Savings assumed to be permanent as retrofitted fixtures will be replaced by equally as efficient fixtures when useful life ends

7. **New Throne for Your Home Program (SF)**
    a. More than 91,000 toilets replaced from 2007 – 2015 (City of Dallas Water Utilities, 2016)
    b. Average of 10,111 toilets replaced each year
    c. Estimated savings of 4,307.7 gallons per year per toilet
    d. Savings assumed to be permanent because toilets will be replaced by equally as efficient toilets due to current plumbing code and efficiency standards

8. **Minor Plumbing Repair Program**
    a. 3,770 families have participated from 2007 – 2015 (City of Dallas Water Utilities, 2016)
    b. Average of 419 households per year
    c. Estimated savings of 6,894.7 gallons per year per household
    d. 2.88 MG stand alone annual savings that accumulates to 26 MG of savings across 9 years of program implementation
    e. Savings assumed to be permanent because fixtures will be replaced by equally as efficient fixtures due to current plumbing code and efficiency standards

9. **Save Water Co. Program**
    a. Project initiated in Dallas's service area in 2015
    b. Save Water Co. completed work on 3,720 multi-family units from 2015 – 2016.
    c. Through personal communication, vendor indicated DWU rebates were occasionally used if the customer qualified, but that many customers that were served did not qualify.

    i. For savings associated with customers that did use DWU rebates, there is a possibility for competitive savings being quantified, or “double counting”

d. These third-party savings are included because the project attempted to capture as much quantifiable savings occurring within a utility’s service area as possible to compare to supply volumes
    i. This particular vendor does a high volume of work in the City of Dallas, so it was deemed reasonable to include its efforts.
e. Average monthly savings of 14.938 MG
f. Annualized savings of 176.26 MG for the life of the retrofitted fixtures
g. This study estimates a lifespan of 25 years for high-efficiency toilet replacements, five years for kitchen aerators and similar devices.
h. Save Water Co. performs monthly meter readings before and after installation to quantify savings.
i. In Region C, the company’s work consists of identifying and repairing all leaks and drips, rebuilding existing toilets and replacing sink aerators.
j. Savings not projected for work that may be completed in the future

5 Summary of savings (implemented through 2016)

Table 5-1. Savings from all activities through 2016 not including water loss reduction (MG).

Year	2x Watering Ordinance	Water Rate Increases	Free Irrigation Inspections (SF/MF/C)	Free Water Efficiency Surveys (ICI)	City-owned Facilities Retrofit	New Throne for Your Home (Residential)	Minor Plumbing Repair Program	Save Water Co.	TOTAL SAVINGS
2009			38.6			130.7	9		178
2010			66.5		0.4	174.2	12		253
2011			101.6		0.9	217.8	14		335
2012	7,179		177.9		1.3	261.3	17		7,637
2013	7,226		190.6	112.3	1.7	304.9	20		7,856
2014	7,273		173.3	224.7	2.1	348.4	23		8,044
2015	7,320		146.7	337.0	2.6	392.0	26	77	8,301
2016	7,367	1,973	143.3	449.3	3.0	435.6	29	179	10,579
2017	7,414	1,985	87.2	449.3	3.0	435.6	29	179	10,582
2018	7,461	1,998	51.3	449.3	3.0	435.6	29	179	10,606
2019	7,507	2,011	26.9	449.3	3.0	435.6	29	179	10,641
2020	7,554	2,023	10.5	449.3	3.0	435.6	29	179	10,684
2021	7,601	2,036		449.3	3.0	435.6	29	179	10,733
2022	7,648	2,048		449.3	3.0	435.6	29	179	10,792
2023	7,695	2,061		337.0	3.0	435.6	29	179	10,740
2024	7,742	2,073		224.7	3.0	435.6	29	179	10,687
2025	7,789	2,086		112.3	3.0	435.6	29	179	10,634
2026	7,836	2,099			3.0	435.6	29	179	10,582
2027	7,883	2,111			3.0	435.6	29	179	10,641
2028	7,930	2,124			3.0	435.6	29	179	10,701
2029	7,977	2,136			3.0	435.6	29	179	10,760
2030	8,024	2,149			3.0	435.6	29	179	10,819
2031	8,118	2,174			3.0	435.6	29	179	10,939
2032	8,213	2,200			3.0	435.6	29	179	11,060
2033	8,308	2,225			3.0	435.6	29	179	11,180
2034	8,403	2,250			3.0	435.6	29	179	11,299
2035	8,497	2,276			3.0	435.6	29	179	11,420
2036	8,592	2,301			3.0	435.6	29	179	11,540
2037	8,687	2,326			3.0	435.6	29	179	11,659
2038	8,781	2,352			3.0	435.6	29	179	11,780
2039	8,876	2,377			3.0	435.6	29	179	11,900
2040	8,971	2,402			3.0	435.6	29	179	12,019
2041	9,066	2,428			3.0	435.6	29	179	12,140
2042	9,161	2,453			3.0	435.6	29	179	12,260
2043	9,255	2,479			3.0	435.6	29	179	12,381
2044	9,350	2,504			3.0	435.6	29	179	12,501
2045	9,445	2,530			3.0	435.6	29	179	12,622
2046	9,540	2,555			3.0	435.6	29	179	12,742
2047	9,635	2,580			3.0	435.6	29	179	12,862
2048	9,730	2,606			3.0	435.6	29	179	12,983
2049	9,825	2,631			3.0	435.6	29	179	13,102
2050	9,920	2,657			3.0	435.6	29	179	13,223
2051	9,996	2,677			3.0	435.6	29	179	13,320
2052	10,072	2,697			3.0	435.6	29	179	13,416
2053	10,148	2,718			3.0	435.6	29	179	13,513
2054	10,224	2,738			3.0	435.6	29	179	13,609
2055	10,301	2,759			3.0	435.6	29	179	13,706
2056	10,377	2,779			3.0	435.6	29	179	13,802
2057	10,453	2,799			3.0	435.6	29	179	13,899
2058	10,529	2,820			3.0	435.6	29	179	13,996
2059	10,605	2,840			3.0	435.6	29	179	14,092
2060	10,681	2,861			3.0	435.6	29	179	14,189
2061	10,719	2,871			3.0	435.6	29	179	14,236
2062	10,756	2,881			3.0	435.6	29	179	14,284
2063	10,793	2,891			3.0	435.6	29	179	14,331
2064	10,830	2,900			3.0	435.6	29	179	14,377
2065	10,867	2,910			3.0	435.6	29	179	14,424
2066	10,905	2,920			3.0	435.6	29	179	14,471
2067	10,942	2,930			3.0	435.6	29	179	14,519
2068	10,979	2,940			3.0	435.6	29	179	14,566
2069	11,016	2,950			3.0	435.6	29	179	14,613
2070	11,053	2,960			3.0	435.6	29	179	14,660

Table 5-2. Savings from Water Loss Reduction (MG).

Year	Utility Population	Water Loss GPCD	Total Savings from Water Loss Reduction
Baseline	-	29.00	0
2015	1,244,270	29.00	0
2016	1,257,730	29.00	0
2017	1,270,170	29.00	0
2018	1,283,120	29.00	0
2019	1,296,070	29.00	0
2020	1,309,020	29.00	0
2021	1,321,970	29.00	0
2022	1,334,920	29.00	0
2023	1,347,870	29.00	0
2024	1,360,820	29.00	0

6 Activities with projected savings

This report contains additional tables not included in other individual reports that project DWU's conservation activities according to feedback received from utility staff. Activities itemized in this section include all active programs contained in the City of Dallas Water Utilities' Water Conservation Five-year Work Plan (2016) with projections suggested by utility staff.

In the summary of projected activity savings in Section 7, for those activities that are ongoing, past savings averages were used to make projections. For future activities, savings estimates in the plan through 2020 were used to project further into the future at the same annual rate.

6.1.1 Financial incentive, device, and fixture activities

1. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
    a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
    b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.
    c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
        i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

2. **Water Rate Increases**
    b. Major rate increase from 2013 – 2016:[16]
        i. 11.125% combined base rate increase
        ii. 11.425% combined volumetric rate increase

[16] Gathered from rates listed in 2013 and in 2016 from documents collected from staff.

iii. 11.275% overall increase with 50/50 weight given to base and volumetric rate increases = 2.255% of total demand

b. Savings are cumulative and based on TWDB's Best Management Practices for Municipal Water Users Guide[17] (Texas Water Development Board, 2013), as well as Environmental Protection Agency guidelines and other sources (U.S. EPA, 1998; Whitcomb, 1999)

3. **Free Irrigation Inspections (SF/MF/C)**
   a. More than 5,700 inspections since program inception
   b. Savings estimated to be 39 MG annually in 2015 (City of Dallas Water Utilities, 2016)
   c. 20% decay rate per year attributed to customer behavior for similar programs (A&N Technical Services, 2005)
   d. Savings projected through 2050

4. **Free Water Efficiency Surveys (ICI)**
   a. More than 320 surveys conducted from 2013 – 2015 (City of Dallas Water Utilities, 2016)
   b. Estimated 107 surveys completed annually
   c. Estimated savings of 1.049 MG per year per audit
   d. Approximately 112.3 MG stand alone peak annual savings, which amounts to 337 accumulated savings across three years (2013 – 2015)
   e. Because some measures implemented during the surveys included equipment, fixtures, and other hardware, assumed a 10-year useful life for savings with no decay rate to be conservative
      i. Savings could persist longer for some hardware items, while behavioral measures could mean savings decay at a faster rate
   f. Savings projected through 2050

5. **City-owned Facilities Retrofit**
   a. From 2010 – 2015, estimated accumulated savings of 2.56 MG annually (City of Dallas Water Utilities, 2016)
   b. Estimated average savings of 426,667 gallons per year
   c. Savings assumed to be permanent as retrofitted fixtures will be replaced by equally as efficient fixtures when useful life ends
   d. Savings projected through 2050

6. **New Throne for Your Home Program (SF)**
   a. More than 91,000 toilets replaced from 2007 – 2015 (City of Dallas Water Utilities, 2016)
   b. Average of 10,111 toilets replaced each year
   c. Estimated savings of 4,307.7 gallons per year per toilet
   d. Savings assumed to be permanent because toilets will be replaced by equally as efficient toilets due to current plumbing code and efficiency standards

[17] Water Conservation Advisory Council (WCAC) estimates 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, we can determine the savings for lower or higher percentage increases.

    e. Savings projected through 2025

7. **Minor Plumbing Repair Program**
    a. 3,770 families have participated from 2007 – 2015 (City of Dallas Water Utilities, 2016)
    b. Average of 419 households per year
    c. Estimated savings of 6,894.7 gallons per year per household
    d. 2.88 MG stand alone annual savings that accumulates to 26 MG of savings across 9 years of program implementation
    e. Savings assumed to be permanent because fixtures will be replaced by equally as efficient fixtures due to current plumbing code and efficiency standards
    f. Savings projected through 2070

8. **Cost Share Program (ICI)**
    a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
    b. Savings projected through 2070
    c. No assumptions made for decay rate or useful life of savings

9. **Toilet Distribution Program (MF)**
    a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
    b. Savings projected through 2040
    c. Savings assumed to be permanent because toilets will be replaced by equally as efficient toilets due to current plumbing code and efficiency standards

10. **Free Toilet Program (ICI)**
    a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
    b. Savings projected through 2050
    c. Savings assumed to be permanent because toilets will be replaced by equally as efficient toilets due to current plumbing code and efficiency standards

11. **Academic and Non-profit Facility Incentives**
    a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
    b. Savings projected through 2040
    c. No assumptions made for decay rate or useful life of savings

12. **Irrigation System Rebate Program (SF)**
    a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
    b. Savings projected through 2050
    c. Assumed useful life of 10 years
        i. Most items available for rebate are irrigation controllers and turf replacements, which have 10-year useful life on average

13. Save Water Co. Program

a. Project initiated in Dallas's service area in 2015
b. Save Water Co. completed work on 3,720 multi-family units from 2015 – 2016.
c. Average monthly savings of 14.938 MG
d. Annualized savings of 176.26 MG for the life of the retrofitted fixtures
e. This study estimates a lifespan of 25 years for high-efficiency toilet replacements, five years for kitchen aerators and similar devices.
f. Save Water Co. performs monthly meter readings before and after installation to quantify savings.
g. In Region C, the company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets and replacing sink aerators.
h. Savings not projected for work that may be completed in the future

6.1.2 Ordinance, Enforcement, and Outreach Activities

14. Twice-per-week (or less) Outdoor Watering Ordinance

a. Estimated savings of 8.42% of total utility demand while ordinance in place (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
b. All savings estimates grow each year at the same rate demand figures for the utility grow in the regional water plan.

15. Enhanced Enforcement (SF)

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2070
c. No assumptions made for decay rate or useful life of savings

16. Enhanced Enforcement (MF)

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2070
c. No assumptions made for decay rate or useful life of savings

17. Enhanced Enforcement (ICI)

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2070
c. No assumptions made for decay rate or useful life of savings

18. Landscape Ordinance Amendment (SF)

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2070
c. No assumptions made for decay rate or useful life of savings

19. Landscape Ordinance Amendment (MF)

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2070
c. No assumptions made for decay rate or useful life of savings

20. Landscape Ordinance Amendment (C)

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2070
c. No assumptions made for decay rate or useful life of savings

21. Increased Outreach Efforts (MF)

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2040
c. No assumptions made for decay rate or useful life of savings

22. ICI and Large Campus Style Properties Targeted Outreach

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2040
c. No assumptions made for decay rate or useful life of savings

23. DWU Residential Rate Calculator

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2070
c. No assumptions made for decay rate or useful life of savings

24. Customer Web and Mobile Applications

a. Annual savings projections provided by DWU (City of Dallas Water Utilities, 2016)
b. Savings projected through 2050
c. No assumptions made for decay rate or useful life of savings

NOTE: Enforcement enhancement activities in Items 15 – 17 likely have a competitive effect on estimated outdoor watering ordinance savings listed in Item 14, which means that savings will be less for these activities in reality than they are when estimated alone in this report. Other outdoor water efficiency measures, such as Items 3 and 4, likely have a similar effect.

7 Summary of projected activity savings

Table 7-1. Savings from all projected activities not including water loss reduction (MG).

Year	Financial Incentive, Device + Fixture Activities	Ordinance, Enforcement + Outreach Activities	TOTAL ACTIVITY SAVINGS
2009	85	0	85
2010	160	0	160
2011	242	0	242
2012	365	7,179	7,544
2013	537	7,226	7,763
2014	679	7,273	7,952

8 Suggested activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs
    - Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

8.1 Suggested activities with savings estimates

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

a. Specific utility results will vary based on portal features and frequency of customer notifications.
b. Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
c. Estimate assumes customers will save 10% of total annual use due to the portal
    i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
d. Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    i. This was the most common percentage of residential use among participating utilities in this project.
    ii. Actual customer class demand percentages will vary by utility.
e. 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
f. Savings are assumed to increase along with demand as connections increase each year.[18]
g. See Table 8-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[18] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 8-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

Statewide Water Conservation Quantification Project
City of Denton Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Denton's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Denton's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Denton's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD[7] consumption and water loss GPCD.[8] [9]

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as

---

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Denton with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.
[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2015	92	120	212	56	21	77	135

2070	340	521	861	1,293	0	1,293	(431)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Denton's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	158	0	0	0
1	2015	131,044	157	29	212	183
2	2016	136,864	157	60	225	165
3	2017	142,684	156	94	233	140
4	2018	148,505	156	130	241	111
5-year Goal	2019	154,325	155	169	249	80
6	2020	160,145	154	210	258	47
7	2021	165,308	154	253	265	12
8	2022	170,471	153	299	272	(26)
9	2023	175,633	153	346	280	(66)
10-year Goal	2024	180,796	152	396	287	(108)

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Denton's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	17.50	0	0	0
1	2015	131,044	17.20	14	120	106
2	2016	136,864	16.90	30	125	95
3	2017	142,684	16.60	47	130	83
4	2018	148,505	16.30	65	136	71
5-year Goal	2019	154,325	16.00	84	141	57
6	2020	160,145	16.00	88	146	58
7	2021	165,308	16.00	91	151	60
8	2022	170,471	16.00	93	156	63
9	2023	175,633	16.00	96	160	64
10-year Goal	2024	180,796	16.00	99	165	66

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
   a. Easy-to-use website with conservation tips and water rates
   b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
   a. The utility engages the public in many ways including:
      i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
   a. Savings of 120 MG annually in 2015
   b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
   c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
   d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Water Rate Increases**
   a. Last rate increases:[17]
      i. 5.0% increase in 2015
      ii. 5.0% increase in 2016
   b. Estimated customer demand reduction of 2.0%
   c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)
   d. Savings from rate increases are shown to persist over time, however, note that savings from these pricing signals will likely decrease if rates remain the same in future years.

5. **Save Water Co. Commercial, Multi-family and Hotel Programs**[19]
   a. Project initiated in service area in 2014
   b. Save Water completed work on 608 multi-family units in 2016
   c. Average monthly savings of 1,431,279 gallons
   d. Annualized savings of 17.17 MG for the life of the retrofitted fixtures

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.
[17] Correspondence with utility staff.
[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.
[19] Savings figures and units serviced based on personal email communication with Kurt Goedrich, December 1, 2016.

e. This study estimates a lifespan of 25 years for high-efficiency toilet replacements, five years for kitchen aerators and similar devices.
f. Save Water Co. performs monthly meter readings before and after installation to quantify savings.
g. The company's work consists of identifying and repairing all leaks and drips, rebuilding existing toilets and replacing sink aerators.

5 Summary of Savings

Table 5-1. Savings by Water Conservation Activity (MG).

Year	Save Water Co. Program	Water Rate Increases	TOTAL SAVINGS
2009			0
2010			0
2011			0
2012			0
2013			0
2014	6		6
2015	12	80.3	92
2016	17	83.1	100
2017	17	85.9	103
2018	17	88.7	106
2019	17	91.4	109
2020	17	94.2	111
2021	17	97.0	114
2022	17	99.8	117
2023	17	102.5	120
2024	17	105.3	122
2025	17	108.1	125
2026	17	110.9	128
2027	17	113.7	131
2028	17	116.4	134
2029	17	119.2	136
2030	17	122.0	139
2031	17	125.1	142
2032	17	128.2	145
2033	17	131.4	149
2034	17	134.5	152
2035	17	137.6	155
2036	17	140.7	158
2037	17	143.8	161
2038	17	147.0	164
2039	17	150.1	167

2021	165,308	15.00	151
2022	170,471	15.00	156
2023	175,633	15.00	160
2024	180,796	15.00	165

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - o The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Twice-a-week Outdoor Watering Restriction Ordinance
   a. Potentially 8.42% savings of total demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and National Wildlife Federation, 2015)
   b. Savings could be 700 MG per year with current demand.
   c. See Table 6-1 for potential savings from this measure compared with the city's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from 2x per Week Watering Ordinance (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Ordinance	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	100	125	225	700	70	26	96	829
2017	103	130	233	723	70	32	101	855
2018	106	136	241	746	84	37	120	867
2019	109	141	249	770	98	42	140	880

2. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[20]
- **g.** See Table 6-2 for potential savings from this measure compared with the utility's WMS supply volumes targets.

[20] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

Table 6-2. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	100	125	225	111	70	26	96	241

3. Rain Barrels

  a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).

  b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
Denton County FWSD #1A Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
    - County-Other (Rural/unincorporated areas of municipal water use)
    - Manufacturing
    - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.

the recommended conservation volumes in the regional plans. This assumption is by no means 100 percent accurate, however. Some previously implemented activities' savings persist into future years beyond this starting point, while some activities' savings have ceased. One year's GPCD will not necessarily include all savings yielded by conservation activities that came before it, but the quantification assessment must have a starting point.

2.3 Quantifiable Savings

The key to the project being useful and reliable is that the results from year to year are measurable. Quantifying conservation activities that can be accurately measured provides greater certainty and better planning for all stakeholders.

While many utilities are engaged in a variety of conservation activities, not all can currently be properly measured. Some examples of these activities include education initiatives, website and social media engagement, and enforcement for water waste. That does not mean these measures are not essential. Education of consumers, for example, is a fundamental activity that makes all others effective, but little hard data exists to quantify the results of education alone.

In addition, the work of conservation coordinators can have a particularly significant effect on the savings of all other activities, but the specific savings attributed to that staff role is difficult to quantify.

3 Results

This report compares Denton County FWSD #1A's current water conservation activities and their quantified savings to two metrics: 1) Region C Water Plan's (Texas Water Development Board, 2016b) recommended WMS supply volumes for municipal conservation, and 2) Denton County FWSD #1A's own 5- and 10-year goals as established in its most recent water conservation plan submitted to the TWDB.

The WMS supply volumes for municipal water conservation are laid out by decade (2020 – 2070) in the regional water plans to serve as benchmarks for what each utility could achieve via that strategy during a 50-year planning period.[5]

The 5- and 10-year goals in Denton County FWSD #1A's most recent water conservation plan are established by the utility as realistic targets for reducing consumption over that timeframe. These reductions[6] are expressed in decreasing total GPCD [7] consumption and water loss GPCD.[8] [9]

---

[5] Some regional water plans separate this strategy volume into a volume for water conservation and a volume for water loss reduction for each decade. The total strategy volume is the sum of both.

[6] Occasionally, some utilities expect consumption to increase due to various reasons, such as an incoming industrial presence expected to raise consumption figures for the entire service area.

[7] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Gallons in System ÷ Permanent Population) ÷ 365

[8] These plans also have targets for residential GPCD and water loss as a percentage (rather than GPCD), but this report does not address those goals.

[9] As defined in TWDB water conservation plan annual report (Texas Water Development Board, 2016o): (Total Water Loss ÷ Permanent Population) ÷ 365

The estimated savings in Tables 3-1 through 3-3 indicate the best information available as provided by utility staff. Some ongoing activities may not be known and are within a utility's service area are implemented on a micro-scale that may not be quantified. Individual households and businesses may be implementing conservation measures that are unknown and therefore cannot be included in the report.

Explanation of approach to assessing water loss reduction savings

Water loss reduction savings are defined as the volume of water participating utilities are realizing from their water loss mitigation efforts. For this report, this value is the difference between each individual utility's baseline[10] for water loss GPCD and its most recent water loss GPCD reported in 2015 water loss audits on file with TWDB. Savings from all water loss reduction efforts—including pipe replacements and leak repair—are assumed to be included in this comparison to a utility's baseline.

Note that because a single year (2015) value was used for comparison, it is possible that the 2015 value could be anomalous due to a number of events that may have occurred that year, such as a water main break, a particularly wet year, or a robust effort by the utility to curtail water loss. This will distort future savings figures that were carried forward in the study because water loss will inevitably increase or decrease in later years.

Ideally, using a rolling five-year average in the calculation would correct such anomalies. However, there was insufficient data to do that for every utility. The approach was to use the most complete water loss data possible, which was represented by the 2015 water loss audit. This problem will be further minimized, as continued data collection will allow five-year averages to be calculated for a majority of utilities.

In this way, water loss savings estimates are different from all other activity savings estimates in the project. Whether savings were positive or negative depended on where individual utilities established their own baselines or where their five-year average started, and what water loss GPCD value was reported in 2015.

3.1 Current Savings Compared to Conservation WMS Supply Volume (in Million Gallons) in Regional Water Plan

Table 3-1 shows the 2070 outlook for Denton County FWSD #1A with the utility's yearly recommended WMS supply volume in million gallons (MG) alongside its water savings from implemented activities, including from water loss reduction. These activities and their associated savings are covered in greater detail in Sections 4 and 5.

Starting in 2015, this table compares all quantified conservation activity and the recommended conservation WMS supply volume for the planning period. The following definitions pair with the column headers in Table 3-1.

[10] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

Actual Current Conservation Activity Savings – All quantified activities currently being performed by the utility, *excluding* savings from water loss reduction. The regional planners used 2011 GPCD as the baseline for determining future conservation WMS supply volumes, therefore the study quantifies utility savings starting in 2012 for this comparison. The summary of these savings can be referenced in Table 5-1.

Actual Water Loss Reduction Savings (as of 2015) – The difference between the baseline[11] for water loss GPCD and most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. [12] The summary of these savings can be referenced in Table 5-2.

Total Savings from All Conservation Activity – Actual Current Conservation Activity Savings plus Actual Water Loss Reduction Savings (as of 2015).

Conservation WMS Volume – The recommended municipal water conservation supply volume in the regional plan for the decades ranging from 2020 to 2070. These volumes are converted to MG from the values listed in the plan in acre-feet and then calculated in annual increments.

Water Loss Reduction WMS Volume – Some regional water plans have a separate WMS volume for water conservation and for water loss reduction for each decade. If a WUG's regional plan has a WMS volume for water loss reduction, this column will have values other than zero.

Total Yearly WMS Volume – The sum of the Conservation WMS Volume and Water Loss Reduction WMS Volume.

Over (Short) – The amount that the utility's Total Savings from All Conservation Activity (since 2012), is over or below the Total Yearly WMS Volume in the regional water plan. If the amount falls below the WMS volume, it will appear in parentheses.

[11] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

[12] If water loss GPCD has increased from the utility's baseline or historic five-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.

Table 3-1. Current Savings Compared to Conservation WMS Supply Volume (MG) in Regional Water Plan.

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)

3.2 Utility Water Conservation Plan Goals – Total GPCD

Table 3-2 shows how Denton County FWSD #1A's quantified savings from its implemented activities compare with 5- and 10-year goals established in its individual water conservation plan submitted to the TWDB. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Total GPCD Goals – Total GPCD goals start with the utility's baseline[13] for total GPCD and progress in subsequent years to match 5- and 10-year goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Annual Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline total GPCD – target total GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings for All Current Quantified Activities (MG) – Total quantified savings for all current conservation activities and savings from water loss reduction. Refer to Tables 5-1 and 5-2 for details on these savings.

Over (Short) – The amount that the utility's total quantified savings for all current conservation activities (since 2012), including water loss reduction, is over or below the volume represented by reductions in GPCD each year. If the quantified savings are less than these target volumes, the value will appear in parentheses.

Table 3-2. Utility Water Conservation Plan Goals — Total GPCD.

Year #	Year	Utility Population	Total GPCD Goals	Annual Savings Goal with Reduction in GPCD (MG)	Total Savings for All Current Quantified Activities (MG)	Over (Short) (MG)
0	**Baseline**	-	230	0	0	0
1	2010	7,371	228	6	-	-
2	2011	8,097	225	14	-	-
3	2012	8,823	223	23	36	13
4	2013	9,548	220	33	44	10
5-year Goal	2014	10,274	218	45	51	6
6	2015	11,000	216	57	123	66
7	2016	11,600	214	69	134	64
8	2017	12,200	211	83	144	62
9	2018	12,800	209	97	155	58
10-year Goal	2019	13,400	207	112	166	54

[13] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for total GPCD from the utility's most recently submitted five-year water conservation plan was used.

3.3 Utility Water Conservation Plan Goals – Water Loss GPCD

Table 3-3 shows how Denton County FWSD #1A's most recent water loss audit compares with 5- and 10-year water loss goals in its water conservation plan. The following definitions pair with the column headers in Table 3-2.

Utility Population – Estimated utility service area population for the years indicated.

Water Loss GPCD Goals – Water loss GPCD goals start with the utility's baseline[14] for water loss GPCD and progress in subsequent years to match 5- and 10-year water loss goals indicated in a utility's five-year water conservation plan on file with the TWDB. The first five annual GPCD goals were developed by spreading the difference between the baseline and five-year goal evenly over five years. The second five annual GPCD goals spread the difference between the five-year goal and 10-year goal evenly over the next five years.

Yearly Savings Goal with Reduction in GPCD (MG) – This column shows what reductions from the baseline water loss GPCD would yield in terms of volume each year as more water is saved. The volumes indicated here are what target water loss GPCD goals look like expressed in million gallons. Annual volumes were derived using the formula: (baseline water loss GPCD – target water loss GPCD for that year) x 365 days ÷ 1,000,000 gallons.

Total Savings from Water Loss Reduction (MG) – The difference between a utility's established baseline for water loss GPCD and the most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB. If water loss GPCD has increased from the utility's baseline to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount. Reference Table 5-2 for savings from water loss reduction.

Over (Short) – The amount that the utility's total savings from water loss reduction is over or below the volume represented by reductions in GPCD each year. If water loss reduction savings are less than these target volumes, the value will appear in parentheses.

Table 3-3. Utility Water Conservation Plan Goals — Water Loss GPCD.

Year #	Year	Utility Population	Water Loss GPCD Goals	Yearly Savings Goal with Reduction in GPCD (MG)	Total Savings from Water Loss Reduction (MG)	Over (Short) (MG)
0	**Baseline**	-	38.00	0	0	0
1	2010	7,371	35.40	7	-	-
2	2011	8,097	32.80	15	-	-
3	2012	8,823	30.20	25	-	-
4	2013	9,548	27.60	36	-	-
5-year Goal	2014	10,274	25.00	49	-	-
6	2015	11,000	25.00	52	64	12
7	2016	11,600	25.00	55	68	13
8	2017	12,200	25.00	58	71	13
9	2018	12,800	25.00	61	75	14
10-year Goal	2019	13,400	25.00	64	78	15

[14] In the absence of having a baseline figure provided by the TWDB or utility staff, the historic five-year average for water loss GPCD from the utility's most recently submitted five-year water conservation plan was used.

4 Implemented Activities

Below is a list of completed activities with estimated water savings. Note that drought response and other measures are not included in the utility's water savings because they are temporary, awareness-based or not able to be accurately quantified on an annual basis.

These are not savings projections of potential future activities. Estimated savings are based on measures that have actually been implemented. If savings are shown to persist in future years, it is because the measure is permanent, such as an ordinance, or the savings are assumed to continue for the reason listed under the itemized activity. Estimated savings from water rate increases are the one exception to these conditions.

Water Rate Increases

Savings from water rate increases were included because entities such as the U.S. Environmental Protection Agency and others indicate specific savings for utilities that raise rates (Texas Water Development Board, 2013; U.S. E.P.A., 1998; Whitcomb, 1999). This project includes surveys of several utilities that have minimal education efforts, perform no other substantive conservation activities, and yet experienced significant demand reduction that coincided with rate increases. In those cases, savings estimates matched up closely with decreases in total GPCD. For many smaller utilities, especially those with customers lacking disposable income, this measure is the only tool used to conserve other than water loss reduction.

The following assumptions were made for water rate increases:

- The model assumes that savings persist into future years because it is expected that the utility will continue to make periodic rate increases in line with the percentage increases from previous years.
- Only the last two rate increases for a utility were quantified.
- Savings grow with demand because as new customers enter the service area, they are assumed to adhere to the same price elasticity model estimates.
- A weighted average for savings was used when rate increases differed between residential and industrial-commercial-institutional (ICI) customers based on the individual utility's customer class breakdown.
- When a utility raised rates using tiered rate conservation pricing, a 50/50 savings split was used when increases differed between base and volumetric rates.
    - The reasoning is that all customers must react to the base increase, yet the pricing signal is stronger when volumetric rate increases affect the higher usage customers.
    - The 50/50 split is reasonable because many customers will not reach the higher volumetric tiers.
    - Studies show that most customers do not actually know they have reached the higher volumetric tiers; just that their bill has increased (Texas Water Development Board, 2013).

4.1 Itemized Activities

1. **Utility Website**
    a. Easy-to-use website with conservation tips and water rates
    b. Features contact information for Public Works staff and customer service

2. **Continuing Public Education**
    a. The utility engages the public in many ways including:
        i. Brochures, bill messages, displays, and exhibits

3. **Water Loss Reduction Savings**[15]
    a. Savings of 64 MG annually in 2015
    b. Water loss reduction savings = the difference between a utility's baseline[16] water loss GPCD submitted in its most recent 5-year water conservation plan and its most recent water loss GPCD reported in the 2015 water loss audit on file with TWDB
    c. If water loss GPCD has increased from the utility's baseline or historic 5-year average to its reported 2015 water loss audit level, then this value will appear negative because more water is being lost than the baseline amount.
    d. All savings estimates grow each year at the same rate population figures for the utility grow in the regional water plan.

4. **Automatic Meter Reading (AMR)/Advanced Metering Infrastructure (AMI)**
    a. These metering systems can save water in a number of ways, including from water loss reduction through improved leak detection.
    b. All water loss reduction savings associated with this activity are detailed in Section 5, which assessed utility baseline water loss GPCD and most recently reported water loss GPCD to determine water savings.
    c. For estimated water savings that could be increased by implementing meter data management (MDM) and customer engagement portal applications, refer to Section 6 of this report.
        i. With these additional applications, water savings can be achieved through changed customer behavior and other real-time actions that go beyond water loss reduction.

5. **Twice-a-week Outdoor Watering Restriction Ordinance**
    a. Estimated savings of 8.0% of total utility demand (Hermitte and Mace, 2012; Sierra Club-Lone Star Chapter and the National Wildlife Federation, 2015)
    b. All savings estimates grow each year at the same rate demand figures for the utility grow in the regional water plan.

---

[15] If current water loss levels exceed a utility's baseline, this value is treated as a deduction from total quantified savings.
[16] In the absence of having a baseline figure provided in the utility's most recently submitted 5-year water conservation plan, the historic 5-year average for water loss GPCD in the plan was used.

5 Summary of Savings

2024	18,408	22.00	108

6 Suggested Activities

Up to four activities were chosen as potential suggested activities for individual reports. These activities are: AMI system with customer portal, twice-per-week (or less) outdoor watering ordinances, strategic water rate increases, and rain barrels.

Activities were chosen because they are:

- Achievable
- Prevalence of vendors that can actually implement them
- Acceptability to city councils, MUD boards, et al.
- Easily adopted
- Cost effective
- Yield high savings relative to cost

AMI systems with customer engagement portals were also chosen because they represent a profusion of future applications that will undoubtedly continue to advance conservation efforts. AMI and meter data management (MDM) companies are developing new and innovative ways to benefit water providers, customers, and ultimately states that are pushing conservation and usage analytics further.

Each utility should be cognizant of the potential impact that these suggested activities may have on its own unique rate and revenue situation.

Benefits to consider:

- Avoided water supply and wastewater costs
    - The higher water purchase, transmission, and distribution costs are, the greater the potential benefit realized when large amounts of water are conserved with these activities.
- Avoided system expansion costs

- Conserving water may allow a utility to postpone building new system capacity by decreasing demand even as population grows.

Costs to consider:

- Staff time and resources
- Unit cost per unit saved
- Implementation costs
- Stakeholder agreement and support
- Other overhead and budget considerations

6.1 Suggested Activities with Savings Estimates

1. Advanced Metering Infrastructure with Customer Engagement Portal

These portals, along with mobile applications and billing statements, can provide customers with much more access to their water use data in simple and compelling formats. This access and comparison with other customers' usage can reduce water use through changed behavior, as well as provide an opportunity for other conservation programs to be offered to the customer for increased adoption and additional savings. AMI systems support leak notification and web portals with real-time data. Any water loss reduction savings that these systems also yield were included in the water loss assessment of individual reports for this project.

- **a.** Specific utility results will vary based on portal features and frequency of customer notifications
- **b.** Potential savings estimate assumes 20% of residential customers will use and save water due to the portal (Westin Engineering, 2015)
- **c.** Estimate assumes customers will save 10% of total annual use due to the portal
    - i. Savings estimate of 10% is an average of results from multiple studies (Chesnutt and Mitchell, 2013; East Bay Municipal Utility District, 2014; IBM, 2011; Texas A&M and Texas Water Resources Institute, 2016; Westin Engineering, 2015)
- **d.** Residential customers' use assumed to make up approximately 67% of all retail customers' use based on utility profile information submitted to the TWDB
    - i. This was the most common percentage of residential use among participating utilities in this project.
    - ii. Actual customer class demand percentages will vary by utility.
- **e.** 20% of residential customers saving 10% with this customer class breakdown amounts to 1.34% of total demand
- **f.** Savings are assumed to increase along with demand as connections increase each year[17]

[17] The 10% consumption reduction figure for 20% of residential customers is conservative, but savings could be greater when monitored yearly as customer engagement increases.

g. See Table 6-1 for potential savings from this measure compared with the utility's WMS supply volumes targets.

Table 6-1. Current Savings + Potential Savings from AMI with Customer Portal (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from AMI with Customer Portal	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	66	68	134	11	9	3	12	132
2017	73	71	144	12	9	4	13	144

2034	183	158	340	31	58	4	61	310
2035	186	161	347	31	61	3	64	314
2036	189	164	353	32	64	2	66	318
2037	193	166	359	32	67	2	69	323
2038	196	169	365	33	70	1	71	327
2039	199	172	372	33	73	1	74	331
2040	203	175	378	34	76	0	76	336

2. Water Rate Increase

a. For every 10% increase, estimated savings could be 2% of utility total demand.

b. Approximately 16 MG of savings per year with current demand

c. Savings is cumulative and based on more than one source[18] (U.S. EPA, 1998; Whitcomb, 1999)

d. See Table 6-2 for potential savings from this measure compared with the utility's conservation goals.

[18] The study estimates a 2% demand reduction with 10% increase in price on a targeted customer class. By applying a ratio, it is possible to determine the savings for lower or higher percentage increases.

Table 6-2. Current Savings + Potential Savings from 10% Water Rate Increase (MG).

Year	Actual Current Conservation Activity Savings	Actual Water Loss Reduction Savings (as of 2015)	Total Savings from All Conservation Activity	Potential Savings from Water Rate Increase	Conservation WMS Volume	Water Loss Reduction WMS Volume	Total Yearly WMS Volume	Over (Short)
2016	66	68	134	16	9	3	12	138
2017	73	71	144	18	9	4	13	150
2018	81	75	155	20	11	5	15	160

2027	147	127	274	37	37	6	43	268
2028	155	133	288	39	40	6	46	281
2029	162	140	302	40	43	6	49	294
2030	169	146	315	42	46	6	51	306
2031	173	149	322	43	49	5	54	311
2032	176	152	328	44	52	5	56	315
2033	179	155	334	45	55	4	59	320
2034	183	158	340	46	58	4	61	325
2035	186	161	347	47	61	3	64	329
2036	189	164	353	47	64	2	66	334
2037	193	166	359	48	67	2	69	339
2038	196	169	365	49	70	1	71	343
2039	199	172	372	50	73	1	74	348
2040	203	175	378	51	76	0	76	352

3. Rain Barrels
   a. In Region C, utilities could save approximately 20.9 gallons per year per gallon of capacity rebated, sold, or distributed (GDS Associates, 2002).
   b. Estimated 10-year useful life for most barrels

Statewide Water Conservation Quantification Project
City of DeSoto Report • 2017

1 Introduction

In Texas' 2017 State Water Plan, municipal water conservation is projected to meet 9.6 percent[1] of the state's future water needs by 2070. According to the 16 regional water plans that comprise the state water plan, this is expected to be achieved through a variety of measures such as installation of water efficient plumbing fixtures, water conservation pricing structures, water system audits, landscape irrigation ordinances, as well as other water conservation activities. The 9.6 percent is "in addition to the estimated share of future passive conservation savings from plumbing codes and water efficiency standards, which are embedded in municipal water demand projections" (Texas Water Development Board, 2017).

In 2015, the Texas Legislature appropriated funds to the Texas Water Development Board (TWDB) to fund a research project principally charged with quantitatively determining the savings of municipal water conservation activities being implemented in relation to the recommended conservation goals (supply volumes) in the State Water Plan. As part of the project, individual reports were completed for all participating utilities.

With this report, utilities will benefit by receiving a clear and concise picture of its water conservation goals alongside estimated savings from quantifiable activities. In the event that current activity savings may not be able to reach long-term goals, this report offers suggestions on how utilities can reach water conservation goals with activities that are effective, easily adopted, have widespread appeal, and are quantifiable.

2 Municipal Conservation Terminology and Review of Methodology Used by Regional Planners

To make use of the results of this study, it is important to understand several key terms used in the water planning process.

What is a water user group?

In this report, a water user group (WUG) refers to a retail water provider in the form a city, municipal utility district, water control and improvement district, special utility district, water supply corporation, fresh water supply district, or other type of water utility. The TWDB further defines WUGs as one of the following (Texas Water Development Board, 2016b):

- Cities and towns with a population of 500 or more
- Non-city utilities providing more than 280 acre-feet per year per year of water for municipal use
- Collective reporting units (CRUs) consisting of grouped utilities having a common association

[1] Equal to 811,224 acre-feet per year in conservation savings.

- County-Wide WUGs:
  - County-Other (Rural/unincorporated areas of municipal water use)
  - Manufacturing
  - Steam electric power generation

What is a recommended water management strategy?

A recommended water management strategy (WMS) is a measure that will help ensure WUGs have adequate water supplies for their end users well into the future. WMS examples include river diversions, groundwater use, reservoir and aquifer development, and irrigation conservation. When WMS is referred to in this report, it refers only to municipal conservation, which may include water loss reduction as a part of the same strategy.

What is a WMS supply volume?

A WMS supply volume is the amount of water that a given strategy is expected to yield each decade in the planning period if carried out by the WUG. In this report, a WMS supply volume is the amount of water recommended to come from municipal water conservation.

Some regional water plans separate this strategy's supply volume into a volume for municipal water conservation and a volume for water loss reduction for each decade. The total strategy supply volume is the sum of both. A regional water plan may also refer to "advanced conservation" as part of this strategy. Advanced conservation usually indicates that the volume could be achieved through a more robust mix of conservation activities described in the plan.

2.1 Regional Planning Group Approach to Determining Supply Volumes

Each regional water planning group (RWPG) is responsible for producing its own individual plan that, if executed, will provide sufficient water to its WUGs throughout a 50-year planning period. These plans are completed in five-year cycles, with the most recent edition being completed in 2016. The 2016 regional plans make up the 2017 State Water Plan, which sets out WMS supply volumes for the years 2020 through 2070.

The decadal WMS supply volumes for municipal conservation were established by each of the RWPGs in much the same manner. The RWPGs generally followed the guidelines of the Texas Legislature's Water Conservation Implementation Task Force on the pace utilities should target to reduce gallons per capita per day (GPCD)[2] consumption levels.

The targeted reductions used by most regions follow this formula:

- For municipal WUGs with water use of 140 GPCD and greater, the goal is to reduce per capita water use by one percent per year until the level of 140 GPCD is reached,

[2] Regional water planning GPCD is defined as the annual volume of water pumped, diverted, or purchased minus the volume exported (sold) to other water systems or large industrial facilities divided by the permanent resident population of the Municipal Water User Group in the regional water planning process divided by 365. Saline and reused/recycled water are not included in this volume (Texas Water Development Board, 2012).

after which, the goal is to reduce per capita water use by one-fourth percent per year for the remainder of the planning period (Texas Water Development Board, 2016j).

The yearly reductions in GPCD for a given WUG are then converted into recommended supply volumes in acre-feet per year for each decade as the reductions in consumption continue. Some regions reduce GPCD by slightly different percentages before and after the 140 GPCD threshold, some do not apply further reductions in GPCD for WUGs once they reach 140 GPCD, while others recommend only "advanced conservation" activities once WUGs meet 140 GPCD.

2.2 Methodology

In order to complete a uniform quantification process, the first engagement was with utilities that agreed to participate and collected as much relevant data as possible. These data included, among many others, historical GPCD consumption figures, advanced metering infrastructure (AMI) specifications, and detailed feedback on each conservation activity being implemented. Personal interviews focused on determining when and to what extent these activities were being employed, as well as assessing plans to continue such conservation. Examples of frequently implemented activities include tiered water rate conservation pricing, strategic water rate increases, outdoor irrigation audits and ordinances, and rain barrel distribution.

Subsequently, each utility's conservation activities were quantified through several different means, including evidence-based studies, utility field results and savings determinations, manufacturer guarantees, water loss audits, TWDB studies, and other information that assigned a savings value to the activity's implementation.

Every conservation activity studied and quantified has a gallons-per-year estimate, useful life, and decay rate (if applicable) associated with it. Some activities' savings are projected to grow as demand grows over time, while some savings are constant each year and subside once useful life has run its course. For expanded methodology and details on studies and formulas used to determine activity savings, refer to Section 6 of the State Report included as part of this document.

Once analyzed, the resulting savings estimates from each utility were compared with the recommended WMS supply volumes in its respective regional plan to determine if the savings met, exceeded, or fell short of those volumes. Individual utility savings were aggregated to compare with regional volumes, and regional savings were aggregated to compare with state volumes.

It is important to note that this report quantified activity savings—not including water loss reduction—for the WMS supply volume comparison dating back to 2012. The reason for this is, with a few exceptions, the regional planners used 2011 as the base year for establishing potential WMS supply volumes.[3] In addition, any conservation savings achieved through 2011 are assumed to be accounted for in the regional water planning GPCD for that year.[4] Thus, quantifying from 2012 and forward is the most accurate way to determine if utilities are meeting

[3] Confirmed via personal communication with Region C, H, K, and L Plan consultants.
[4] It was established with TWDB planning staff that 2011 GPCD levels were chosen because they represented the most current water use and conservation patterns at the time.
