## **1.0.0 PROJECT OVERVIEW**

The purpose of this project was to collect water circulation data in Nueces Bay in order to assess circulation patterns in the area and provide the baseline data needed to determine how freshwater inflows are moving within the bay. Specifically, this project consisted of:

1. Deployment of an array of 10 tilt current meters covering Nueces Bay from SALT01 west to the Nueces Delta, the lower portion of the Nueces River, and the mouth of Rincon Bayou
2. Quality control of all collected circulation data
3. Generation of data summaries and visualization tools

There is great interest in how freshwater input patterns affect the Nueces Estuary. When combined with water quality and biological monitoring data, circulation data may provide important additional insights into how freshwater inflows influence the ecology in different areas of the system. Current pattern data gathered in Nueces Bay will also be valuable for both the validation of existing circulation models for the bay, such as the Texas Water Development Board's TxBLEND model, and for the development of future circulation models for the bay.

Over 1 year of continuous circulation monitoring data was collected in Nueces Bay from June 29, 2016 to September 3, 2017 using tilt current meters. Tilt meters are novel in that their low cost allows multiple instruments to be deployed in an array so that spatially synoptic data can be gathered. They also lack external moving parts, which makes them less susceptible to data loss from fouling than mechanical flow meters.

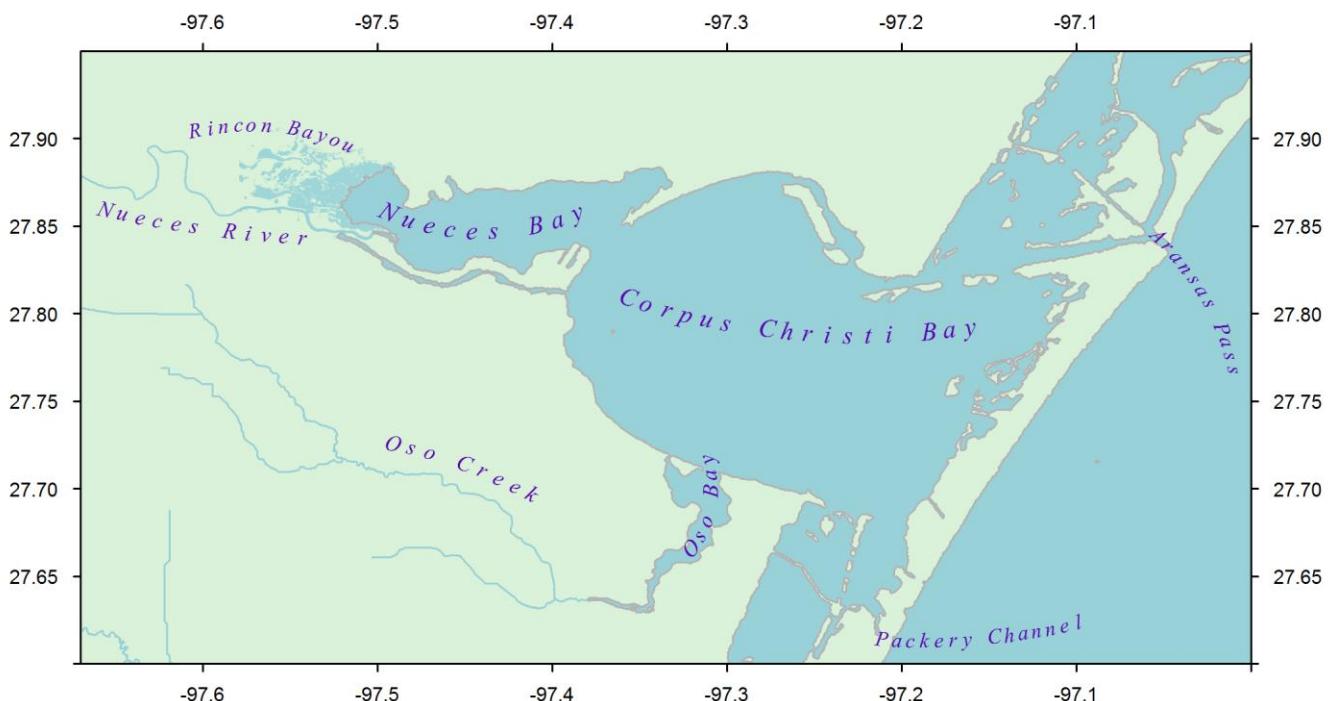

An array of 10 tilt meters was deployed over the back end of Nueces Bay from SALT01 west to the Nueces Delta. Meters were also placed at the Nueces River mouth and at the entrance to Rincon Bayou from Nueces Bay to assess water exchange between the main inflow connections and the bay.

The tilt meters were retrieved roughly every two weeks to remove fouling and offload data. Raw data from the meters was manually processed and subjected to quality control procedures. The final results include baseline data for water circulation patterns in upper Nueces Bay and visual representations of current movements at the monitoring stations under various conditions (wind, tide, freshwater inflow events).

## 2.0.0 BACKGROUND

### 2.1.0 Study area

Nueces Bay is the uppermost bay within the Nueces Estuary, which consists of consists of Nueces Bay, the Nueces River, Oso Bay, Oso Creek, and Corpus Christi Bay (Figure XX). Mustang Island and North Padre Island limit water exchange between the Nueces Estuary and the Gulf of Mexico to two passes: Aransas Pass near the northeast corner of Corpus Christi Bay and Packery Channel near the southwest corner of Corpus Christi Bay. Several smaller passes on Mustang Island linking Corpus Christi Bay to the Gulf of Mexico (Newport Pass, Corpus Christi Pass, and Fish Pass) are primarily closed. In addition to the limited connectivity of Nueces Estuary to the Gulf of Mexico, Nueces Bay's secondary status to Corpus Christi Bay and its shallow depth (~0.5 m average) result in notable tidal attenuation in the bay, such that the semidiurnal component observed in other parts of the system is filtered out and only diurnal tides are observed.

**Figure XX** Map of the Nueces Estuary.

Nueces Bay receives freshwater inputs from the mouth of the Nueces River on its southwest shore and exchanges water with the Nueces delta along its western shore. The Nueces delta receives freshwater input via overbanking of the Nueces River into Rincon Bayou during flood events. A channel constructed between the river and Rincon Bayou just south of Calallen is intended to improve freshwater inflow to the Nueces delta. River flow to the Nueces Estuary is impacted by two large reservoirs in the Nueces River Basin, Choke Canyon on the Frio River and Lake Corpus Christi on the Nueces River.

## 2.2.0 Tilt current meters

OkeanoLog SeaHorse tilt current meters consist of a buoyant 2.5 cm diameter PVC rod with a HOBO® Pendant G Data Logger fixed to the top and a 4 cm flexible tether to moor the meter at the bottom. These tilt current meters are well adapted for use in shallow estuaries. Their relatively low cost allows for the deployment of multiple meters in different locations, and internal data storage allows them to be deployed for extended periods of time. They also lack external moving parts, which makes them less susceptible to data loss from fouling than mechanical flow meters. Data collected during side-by-side field deployments of tilt meters and acoustic Doppler current meters have shown very good agreement between the two instruments despite their vast difference in complexity (unpublished data).

**Figure XX** Pre-deployment photograph of a tilt current meter attached to its tether and a close-up of the HOBO pendant underneath the cap on top of the meter.

The waterproof pendant at the top of each meter contains a three-axis accelerometer that measures acceleration in gravitations along an x-, y-, and z-axis. These measurements indicate how much the instrument is leaning as it is pushed by the current. The pendant is equipped with 64K bytes of memory and can log at various rates ranging from multiple times per second to once every 18.2 hours. The amount of time it takes for the pendent memory to fill depends on the logging rate. Data is read from the pendant via an optical USB connection, which allows for data offload without the need to break the waterproof seal. An adapter can transfer data directly from the pendant to a computer, or data can be read out onto the HOBO® Waterproof Shuttle and later transferred to a computer. The raw data files are in .hobo format and must be offloaded, opened, and saved using HOBOware Pro software.

OkeanoLog provides its own software for converting the acceleration values offloaded from the instruments to North and East velocity vectors. The software runs in Python, must be calibrated for the region in which the meters will be deployed, and requires configuration files for the model number and serial number of each tilt meter it will be converting data from.

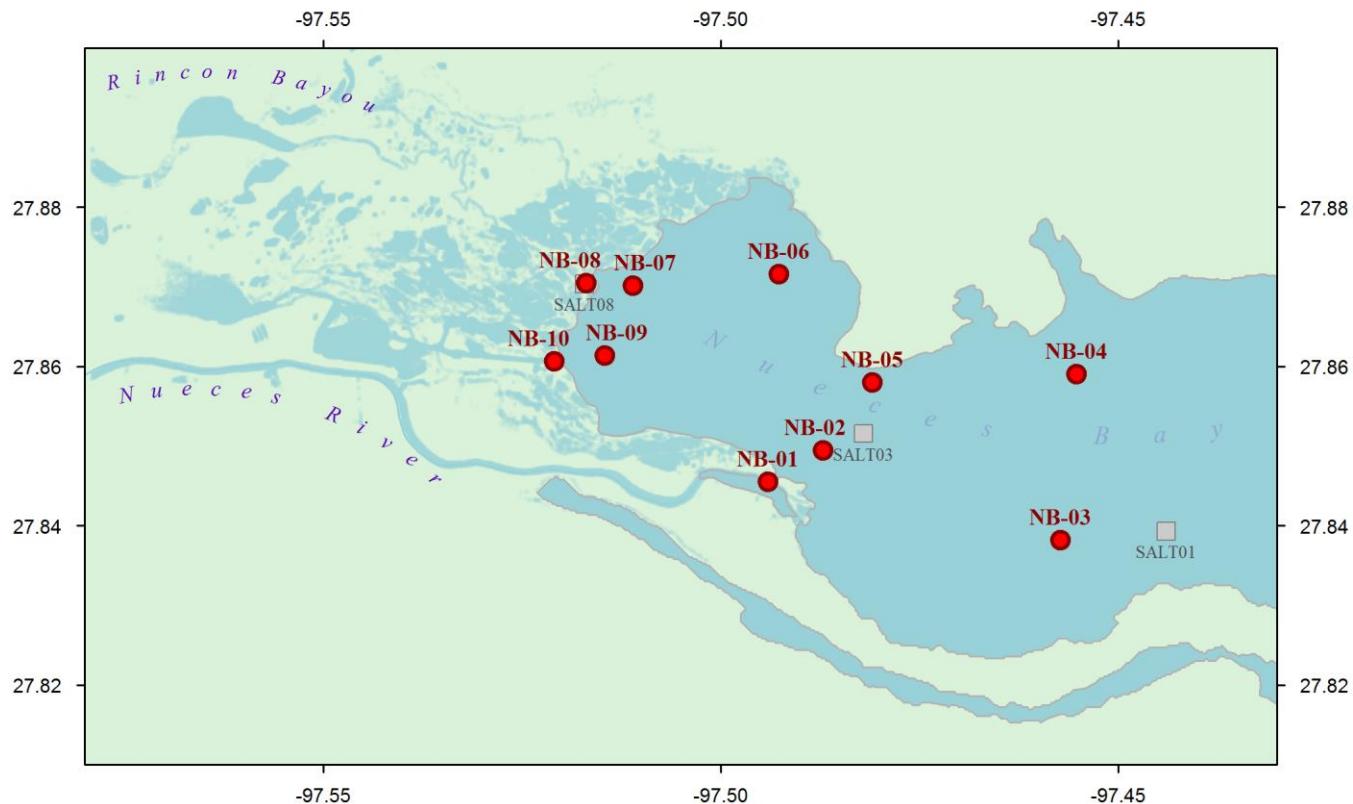

Documents that include detailed descriptions and instructions for using the tilt meters, HOBO pendants, and OkeanoLog conversion software are included in the Documentation and Data Package submitted with this report (see Appendix A).

### 3.0.0 METHODS

#### 3.1.0 Monitoring stations

Potential monitoring stations at which to deploy current meters were scouted on June 17, 2016 to assess their depth and whether any structures were nearby that might affect flow measurements. It was necessary for selected monitoring stations to have a water depth of at least 50 cm during low tide to accommodate the tilt meters and for them to be relatively clear of any reefs or sandbars that might obstruct flow.

A total of 10 monitoring station locations were selected in the upper Nueces Bay. Stations were assigned names consisting of “NB” appended with a number 1-10 in roughly a counter-clockwise pattern starting at the mouth of the river (Figure XX). Station NB-01 was therefore located at the mouth of the Nueces River. Station NB-08 was located at the entrance to lower Rincon Bayou adjacent to the City of Corpus Christi’s SALT08 salinity monitoring station, and NB-10 was located at the entrance to the channel leading to the US Army Corps of Engineers Nueces Delta Mitigation Project site and South Lake. The other 7 stations were distributed within the bay in areas relatively clear of reefs or other obstructions. NB-03 and NB-10 were deepest on average, each with a mean measured depth of 1.8 m, and NB-9 was the shallowest station, with a mean depth of 1.1 m (Table XX).

**Figure XX** Map of final current monitoring stations in Nueces Bay (red points), as well as the locations of City of Corpus Christi Salinity Monitoring stations SALT01, SALT03, and SALT08 (gray squares).

**Table XX** Brief location description and average longitude, latitude, and depth of each tilt meter station.

Station	Longitude	Latitude	Depth (m)	Description
NB-01	-97.49399	27.84553	1.6	just inside mouth of Nueces River
NB-02	-97.48705	27.84947	1.6	600 meters NE of Nueces River mouth
NB-03	-97.45725	27.83821	1.8	southeastern-most station, approximately mid-bay
NB-04	-97.45521	27.85901	1.7	northeastern-most station, approximately mid-bay
NB-05	-97.48090	27.85798	1.2	parallel station ~1.1 km NE of NB-02
NB-06	-97.49267	27.87157	1.3	northern portion of upper bay
NB-07	-97.51099	27.87014	1.2	500 meters E of Rincon Bayou exchange channel
NB-08	-97.51688	27.87050	1.7	adjacent to SALT08 salinity monitoring station within Rincon Bayou exchange channel
NB-09	-97.51452	27.86135	1.1	eastern-most portion of upper bay
NB-10	-97.52086	27.86067	1.8	at entrance to channel leading to Nueces Delta Mitigation Project site and South Lake

### 3.2.0 Deployment and retrieval

Tilt meter models vary in length. The depths of the final monitoring stations selected determined the lengths of the tilt meters that could be placed at them. The tilt meters used in this study were 50, 25, and 10 cm long (Table XX). The 50 cm long meters were ballasted models for use in areas with currents <30 cm s<sup>-1</sup>.

**Table XX** Details for individual meters deployed during this study, including which stations they were deployed at and their status at the end of the study.

Owner	Purchase date	Model	Serial number	Length (cm)	Station	Final status	Notes

Prior to deployment, the data loggers on the tilt meters were set to record acceleration and angular displacement in 3 axes once every two minutes. In the field, the tethers at the base of the meters were attached to 1 m long, 2.5 cm (1 inch) diameter PVC stakes (Figure XX), and a pole extendable to 2.5 m was used to drive the stakes into the sediment from the boat. After setting each stake, a weight attached to the stake with a 9 m long polypropylene rope was dropped as far away from the meter as possible, and the locations of both the meter and the weight were marked as waypoints on a handheld GPS unit. This deployment technique allowed for meter recovery without the need for surface markers, which tend to attract unwanted attention from boaters and fishermen.

**Figure XX** Pre-deployment photograph of the tilt meter deployment assembly consisting of the meter tethered to a PVC stake and a weight attached to the stake with a polypropylene rope.

The meters were retrieved roughly once every 2-4 weeks (2 weeks during warmer seasons, 4 weeks during cooler seasons) to offload data and check for fouling. A grappling hook was used to snag the rope strung between the meter and the weight at each station, and the rope was used to pull the stake loose from the sediment and bring the meter to the surface. A HOBO® Waterproof Shuttle was used to offload data from the loggers in the field and reset them for immediate redeployment after the removal of any fouling. Instruments that were damaged or missing were replaced if extra tilt meters were available.

Scans of the field datasheets that were used to record the serial numbers of the instruments deployed at each station, the station depths at the time of deployment, fouling extent and type on recovered instruments, and other deployment/retrieval notes are included in the Documentation and Data Package submitted with this report (see Appendix A). All field metadata were transferred to a csv file included in the Documentation and Data Package and are also given in Appendix B.

All offloaded data were backed up to a hard drive upon return to the lab.

### 3.3.0 Data processing

#### 3.3.1 Raw data files

Data files were offloaded from the waterproof shuttle using Onset Computer Corporation HOBOware® Pro 3.7.4 software and saved as text files. Data in the text files were examined using R statistical software (R Core Team 2015), data values logged while the instrument was out of the water at the beginning and end of each deployment were trimmed from the time-series, and the data were re-saved in files named with the deployment ID, station number, and meter serial number (e.g., NERR-20170320\_NB-04\_SN10113984.txt). The raw .hobo files, raw .txt files, and trimmed .txt files are included in the

Raw\_Hobo\_Files\_Nueces, Raw\_Text\_Files\_Nueces, and Formatted\_Text\_Files\_Nueces folders of the Documentation and Data Package.

### 3.3.2 *Tilt to velocity conversion*

The trimmed text files were run through custom OkeanoLog Python (Python Software Foundation 2015) scripts to convert the acceleration and tilt data to north and east velocity vectors. For conversion, each meter requires a calibration file specific to the model number, as well as a calibration file specific to the instrument serial number. The model calibration files were provided by OkeanoLog. For the serial number calibration files, instrument-specific 0 and 1 g offsets and 0 velocity offsets were estimated by examining the extreme values of all data recorded by each logger and by taking the median values of near-0 x- and y-axis readings during deployment, respectively. All calibration files, Python scripts, trimmed raw text files, and converted text files are included in the Python\_Seahorse\_HOBO folder of the Documentation and Data Package.

### 3.3.3 *Fouling effects and direction adjustments*

R was used to examine the converted data to determine approximate dates at which fouling noticeably began to affect the velocity readings (most visually apparent in cumulative sum plots of current speed over time) and to calculate any direction alignment adjustments that needed to be made for each meter on each deployment. Although an effort was made to always align the y-axis of the logger on each meter to North, it was difficult to be exact with orientation when deploying the instruments. Misalignment could result from several factors, including slight rotation of the meters on their tethers, slight rotation of the mooring stake within the deployment tube while the stake was being pushed into the sediment, and rotation of the mooring stake if too much tension was applied to the attached rope when the weight at the other end was being strung out.

To calculate direction adjustments, the recorded direction data were aligned with water level data from the NOAA monitoring station 8775296 at the USS Lexington in Corpus Christi Bay (<https://tidesandcurrents.noaa.gov/stationhome.html?id=8775296>). The water level data for this station are well-correlated with the water depth data taken at the SALT salinity monitoring stations within Nueces Bay (with the SALT station water depths lagging the Lexington water levels by ~1.5-2 hours), and the Lexington time-series is more complete. Tilt meter current directions were divided into 15 degree bins and the number of measurements in each bin aligned with the highest and the lowest daily water level quantiles were tallied. The number of degrees each dataset needed to be rotated to align with the overall median high and low water level directions for each station was then calculated. Direction adjustment estimates were done for each station except NB-06, where current speeds were generally too low to get reliable direction readings.

The direction adjustment and fouling begin date for each data file, along with other information such as temporal coverage, were recorded in the TiltMeter\_Metadata\_DataFiles.csv file included in the Documentation and Data Package. Most of the information in the metadata file is also included in

[Appendix C](#). Plots depicting the water level-based direction corrections made for each station on each deployment are included in [Appendix D](#).

## 4.0.0 DATA SUMMARY

### 4.1.0 Temporal coverage

Sampling occurred from June 29, 2016 to September 3, 2017. Damage and loss of some instruments caused data gaps for various periods at some stations (Table XX).

**Table 4-1** The serial number of the meter logging at each station during each deployment. Serial numbers are only listed if a data file was successfully retrieved from the meter at the end of the deployment.

### 4.4.0 Patterns

Velocity data were smoothed using a 1 hour running average prior to analysis. All analyses described below were done in R.

Average current patterns under different environmental conditions were determined.

Animations of the data were generated to help visualize spatial and temporal patterns of flow among the stations.

## **REFERENCES**

## **APPENDIX A: DOCUMENTATION AND DATA**

The following is the README file content for the documentation and data package submitted with this report. It depicts the structure of the package and contains descriptions of the included folders and files.

## APPENDIX B: FIELD METADATA

The following table shows the content of the **Tilt\_Meter\_Metadata\_Deployments.csv** file included in the Documentation and Data Package submitted with this report. Fouling index is a scale ranging from 0 for no fouling to 4 for 100% instrument coverage. The Data file names are the names of the raw .txt files converted from the .hobo files offloaded from the HOBO® Waterproof Shuttle. These raw .txt files can be found in the Raw\_Text\_Files\_Nueces folder of the Documentation and Data Package.

Deployment ID	Date deployed	Time deployed (gmt)	Station	Meter sn	Lat	Lon	Depth (m)	Notes deployment	Date retrieved	Fouling index	Fouling type	Notes retrieval	Data file

## APPENDIX C: DATA FILE METADATA

The following table shows the content of the **Tilt\_Meter\_Metadata\_DataFiles.csv** file included in the Documentation and Data Package submitted with this report. Information included in the file but omitted here includes the minimum and maximum timestamp values recorded, the time format of the raw data file (either GMT-05:00 or GMT-06:00), and the time format of the formatted data file (always GMT-6:00).

The names in the Raw file name column correspond to the file names in the Raw\_Text\_Files\_Nueces folder. The corresponding Formatted\_Text\_Files\_Nueces file names consist of the Deployment ID, Station, and Meter SN of each data file. For example, the Formatted\_Text\_Files\_Nueces file that corresponds to the first file listed in the table is NERR-20160629\_NB-01\_10505035.txt.

The Deploy data column indicates whether the file includes valid velocity readings, the Duplicate file column indicates whether the file is a duplicate (some files were backed up multiple times), and the Deploy start and end columns show the temporal coverage of the deployment velocity data in the file. The Direction adjustment column contains the values, in degrees, to be added to the direction values in each data file to correct for instrument misalignment in the field. The dates in the Fouling date start column are the dates where fouling appears to begin to influence velocity readings. Fouling effects were not evident in most of the data files.

Raw file name	Deploy data	Duplicate file	Deployment ID	Station	Meter SN	Deploy start	Deploy end	Direction adjustment	Fouling date start

## APPENDIX D: CURRENT DIRECTION ADJUSTMENTS

The following plots depict the direction adjustments made to the current data at each station for each deployment. Each segment represents a 15 degree direction bin. Segment lengths indicate mean velocity of water moving in the respective direction (a scale value giving the maximum value of the x- and y-axes is given for each set of plots). Segment colors differentiate between bins dominated by measurements made during high water (blue), low water (orange), or neither (gray). Segment transparency represents the relative number of all values falling into the direction bin, with darker segments representing more values.

To calculate the adjustments, the direction data were aligned with water level data from the NOAA monitoring station 8775296 at the USS Lexington in Corpus Christi Bay (<https://tidesandcurrents.noaa.gov/stationhome.html?id=8775296>). Alignment was accomplished by shifting the time-series by whichever lag produced the highest absolute cross-correlation coefficient between the direction data and water level data. The direction data for each deployment at each station were divided into 15 degree bins and the number of measurements in each bin aligned with the highest and the lowest daily water level quantiles were tallied. The number of degrees each dataset needed to be rotated to align with the overall median high and low water level directions for each station was then calculated. Direction adjustment estimates were done for each station except NB-06, where current speeds were generally too low to get reliable direction readings.
