CALHOUN COUNTY, TEXAS

Introduction

By

W. O. George, Assistant Geologist  
United States Geological Survey

This publication contains records of 266 wells, 45 test wells, 36 drillers' logs and 312 chemical analyses of water obtained from the wells.

In 1935, a memorandum on the ground water in Calhoun County, Texas, together with records of wells, drillers' logs, and water analyses, and a map showing location of wells, by John T. Lonsdale, was released in photostatic form by the United States Department of the Interior, Geological Survey in cooperation with the Texas Board of Water Engineers and Engineering Experiment Station of Agricultural and Mechanical College of Texas. Only a few photostat copies were released for distribution.

On January 3, 1940 the Work Projects Administration started a more complete inventory supplemented by a program of test hole drilling, sponsored by the State Board of Water Engineers in cooperation with the Federal Geological Survey, with Carl E. Johnson as project supervisor. The field work was completed in August 1940.

Mr. Lonsdale's memorandum is included in this release. Nearly all of the wells observed by Mr. Lonsdale were revisited by Mr. Johnson and changes in water levels were recorded and additional water samples were obtained for more complete analyses. The map has been revised but the wells observed by Mr. Lonsdale retain the same numbers as were shown on the original map.

The analyses were made by chemists employed on Work Projects Administration Project No. 17276 under the direction of Dr. E. P. Schoch, Director of the Bureau of Industrial Chemistry, University of Texas, and E. W. Lohr, Chemist of the Quality of Water Division of the Federal Geological Survey. The Bureau of Industrial Chemistry furnished laboratory space and equipment. The analyses in this release are tabulated in parts per million. A number of these analyses are also given in milligram equivalents per liter for the convenience of those who prefer this form of expressing the quality of water.

This release was typed by typists employed on Work Projects Administration Project No. 17276.

The records serve as a guide to land owners, well drillers and others who need information regarding wells, the depth to ground water in different parts of the county, and the quality and chemical character of water yielded by the wells. They afford a basis for the more intensive investigation that is now being carried on by the State Board of Water Engineers in cooperation with the Federal Geological Survey.

- i -  
Ground water in Calhoun County, Texas

By John T. Lonsdale

### Introduction

The brief report that follows is based chiefly on a study of records of wells in Calhoun County obtained in June, July, and August, 1934, for the most part by the writer, but in part by J. C. Cumley, junior engineer in the United States Geological Survey under an appointment by the Administrator of Public Works. Older published data relating to the geology and occurrence of ground water in the county given by Taylor <sup>1/</sup> and Deussen <sup>2/</sup> together with unpublished information obtained by Deussen <sup>3/</sup> have also been consulted. Most of the well data that have been obtained are given in the accompanying tables. The location of the wells is shown on the accompanying map, each well being given a number that corresponds to the number assigned to it in the tables. The data in the tables relating to the chemical character of the well waters were determined from tests and partial analyses in the Water Resources laboratory of the Geological Survey at Washington, D. C. (See pages 51 and 52).

### General description of Calhoun County

Calhoun County borders on the Gulf of Mexico and is approximately midway between Corpus Christi and Freeport. It has an area of about 560 square miles, of which bays and lagoons comprise approximately one-half. It includes all of Matagorda Island, an offshore bar that has an area of approximately 50 square miles.

The county is part of a region of considerable historic interest, some of the important events in Texas history having occurred here. Indianola, destroyed by a hurricane in 1876, was the port of entry for many of the earlier immigrants to Texas, and was an important coast town for many years. Port Lavaca, the county seat, was shelled by United States gunboats during the Civil War.

In 1930 the county had a population of 5,385, and Port Lavaca, the county seat and largest town, had 1,837. The smaller towns are: Seadrift, Port O'Connor, Long Nott, Green Lake, Heyser, Olivia, and Kamey. Approximately three-fourths of the mainland part of the county is devoted to ranching. The remainder is farmed, the chief crop being cotton. Matagorda Island is used only for ranching. An important seafood industry centers around Port Lavaca, Port O'Connor, and Seadrift.

### Topography and drainage

The surface of the county slopes southeastward toward the Gulf, northern parts of the country having altitudes of about 45 feet. Along the coast, in some places, there is a wave-cut cliff 18 to 22 feet high, but in others the slope is gradual. The area landward from the top of the wave-cut cliff at the same elevation or higher forms the Beaumont terrace. Other less distinct terraces exist in the area. Guadalupe River, which forms the western boundary of the county, and Lavaca River are the principal streams. A part of the land between these streams has very poor natural drainage and is artificially drained by an extensive canal system.

<sup>2/</sup> Deussen, Alexander, Geology of the Coastal Plain of Texas west of Brazos River: U. S. Geol. Survey Prof. Paper 126, 1924.

<sup>3/</sup> Deussen, Alexander, Unpublished well data in the files of the U. S. Geological Survey at Washington, D. C., obtained in 1913.

Rainfall

According to records of the United States Weather Bureau the average rainfall at Lavaca during 14 years (1901-1913, and 1926) amounted to 36.16 inches, of which about 25 inches occurred during April to October, inclusive.

Geology

The geologic formations exposed at the surface in Calhoun County are: the Beaumont clay (Quaternary), and Recent stream and terrace deposits. The Beaumont consists of deltaic deposits of yellowish, bluish, gray, and pink clays with subordinate amounts of yellowish and bluish sands. Its outcrop area includes most of the northern and central parts of the county. It has its maximum thickness near the coast but even there probably does not exceed 250 feet. The Beaumont is underlain by the Lissie formation (Quaternary) and the Lissie in turn is underlain by the Goliad (Pliocene) sand. These formations are exposed in Victoria and Jackson Counties which adjoin Calhoun County on the north and are reached by wells at various depths throughout the county. They consist of sands and gravels with interbedded clays and probably have a combined thickness of at least 1,500 feet. Recent river and coastal alluvium deposits extend far up the Guadalupe River and, together with wind blown sand occupy an extensive belt along the coast.

The exposed and unexposed formations dip to the southeast at very low angles. The beds in the Beaumont clay probably have a dip that is not much greater than the slope of the present land surface, but underlying beds have a somewhat steeper dip. Although considerable drilling for oil has been carried on in the area, there is no authentic report of abnormal subsurface structural conditions.

Water-bearing sands and gravels and well development

The entire county is underlain by water-bearing beds of sand and gravel in the Beaumont clay, Lissie formation, and Goliad sand and in parts of it the sands in Recent deposits also carry water. Generally, in a given area several water-bearing beds, ranging in depth from a few feet to several hundred feet, are encountered by wells. Well drilling in the county has been controlled by the quality and quantity of water desired for a given use. Domestic farm wells require only a small supply but the water must be potable. Ranch wells for large herds of stock require larger supplies, but a greater range in quality is permissible. The type of well development in parts of the county has also been largely determined by local drilling conditions. Wells throughout the county either have a flow or the water levels in them are within a few feet of the surface.

Seventy-three flowing wells were visited representing, it is estimated, about 80 percent of the flowing wells of the county. The reported depths of these wells (see tables of well records) are as follows: five less than 300 feet; twenty-four between 300 and 400 feet; twenty-three between 400 and 600 feet; nineteen between 600 and 900 feet; two more than 900 feet. The static levels in the flowing wells were found to range from a fraction of a foot to about 19 feet above the surface. Based on measurements made in the course of the investigation, or reliable records of measurement by the owner or other persons, the discharge of the wells in gallons a minute is as follows: twenty-six less than 10; thirty-two from 10 to 20; four, more than 20; one (No. 56) 50. It is estimated that the total flow of all the wells visited amounts to approximately 700 gallons a minute.

Flowing wells could probably be obtained in all parts of the county by drilling to a sufficient depth. Areas in which flowing wells are most common are as follows: (1) The northwestern part of the county where the Goliad sand is a source of artesian water; (2) the peninsula between Lavaca Bay and Carancahua Bay; (3) the area east of Carancahua Bay; (4) the southern part of the county, south of a line between Port Lavaca and Seadrift. The north-central part of the county does not

have flowing wells partly because the surface is somewhat high so that wells shallower than 500 feet will not flow, and partly because the area is a farming one in which small wells are adequate for domestic supply and a few head of stock, and therefore no particular need has thus far developed for putting down deep wells.

The well water is used principally for domestic purposes and for watering stock. The public supplies of Port Lavaca and Port O'Connor are from wells. A few small gardens are irrigated and several cotton gins are supplied from wells.

#### Well-drilling methods

The deeper wells and many of the shallow ones have been drilled with rotary outfits capable of drilling to depths of approximately 1,000 feet, the principal difficulty encountered in the deeper drilling being to keep the drill stem free in the soft poorly consolidated formations that underlie the area. As in many Texas localities, one or two drillers have put down most of the deeper wells and the methods used in drilling and completing the wells is a result of their individual experience. Many shallow bored wells have been put down by the property owners themselves. In such wells 2 to 3 inch casing is generally used and in many instances the pump cylinder is placed above the ground and rests on the end of the casing.

Galvanized iron casing is used in practically all the cased wells, since it resists corrosion better than other types. In the deeper wells it is usual to set 8 to 20 feet of screen in the water sand, but in many of the shallow wells no screen is used and the open end of the casing is set in the sand. There are comparatively few dug wells in the county..

#### Quality of well waters

The water from most of the wells of the county are comparatively highly mineralized, waters with a distinct saline taste being common. The chloride content and hardness of the water in different localities and at different depths, however, vary within fairly wide limits whereas the bicarbonate remains fairly constant. The quality of the water in individual areas is briefly discussed in the pages following.

#### Ground water in individual areas (See map and tables of well records, drillers' logs, and analyses)

Heyser. - The upland part of this area is underlain by a thin cover of Beaumont clay beneath which the Lissie and Goliad sands are encountered. The lowland part in the valley of the Guadalupe River is underlain by Recent deposits. Records of 21 wells, including 2 oil tests, were obtained in the area. The water wells range in depth from 45 feet to 928 feet, and those that are more than 400 feet have a flow. In the shallow wells the water levels are from 25 to 50 feet below the surface. The deepest wells draw from sands that are more than 700 feet below the surface, although they penetrate water-bearing sands at shallower depths. In 12 of the 13 deep wells from which samples were taken, the waters contain chloride ranging from 310 to 482 parts per million; hardness, from 45 to 120, and bicarbonate from 298 to 408. The water from one deep well (No. 11) contains 1,090 parts per million of chloride. The water from the 3 shallow wells Nos. 1, 2, and 21 average somewhat lower in chloride and much higher in hardness than that from the deep wells.

Kamey. - The wells that are deeper than 250 feet in this area probably derive water from the Lissie-Goliad sands, and the shallower wells from sands in the Beaumont. Thirteen water wells, ranging from 21 to 630 feet in depth, were visited in the area. One flowing well (No. 36, 630 feet deep) was found. The water level in the nonflowing wells ranges from 12 to 26 feet beneath the surface. The water

from most of the wells is highly mineralized. Wells 30 and 31, 250 feet deep, yield water that is fresher and softer than that from the other wells visited in the district. The water from the flowing well is so salty that it could be classed as almost a brine.

Olivia.- Twenty-six wells were visited in this district of which 22, ranging in depth from 262 to 620 feet, have a flow. Very few shallow wells have been used in the area since it was demonstrated, about 1908, that good artesian water could be obtained at fairly shallow depths. Of the two deep wells that do not have a flow one is on relatively high ground and the other is finished in a comparatively shallow sand at 203 feet. Well 71 was found to have the highest artesian head of any of the wells visited in this vicinity, the water in it rising to about 27 feet above sea level. Well 56 flows at 19 feet above the well mouth, but the well is located only slightly above tide level. It is reported that the artesian head has dropped about 2 feet and the yield of the wells declined since the first well was drilled in 1907. The water from the flowing wells in this area averages fresher and softer than the water from any group of wells in the county.

Green Lake.- The depths of the 17 water wells visited in this area are as follows: 10 from 35 to 90 feet; 6 from 216 to 268 feet; one 580 feet. The waters from the shallow wells contain chloride ranging from 50 to 930 parts per million, and hardness ranging from 270 to 1,000 parts per million, while those from the deeper group contain chloride ranging from 650 to 1,090 parts per million, and hardness from 360 to 550 parts per million. The water from the 580-foot well has 2,380 parts of chloride and 1,000 parts of hardness.

Port Lavaca.- The depths of 23 of the 25 water wells visited in this area are as follows: 7 from 20 to 60 feet; 13 from 203 to 375 feet, and 2 between 800 and 900 feet. Three of the wells that are only a few feet above tide level have a flow. In much of this area all the sands that have been exploited contain water that is highly mineralized. The freshest and softest water sampled in the area comes from wells that are several miles west of Port Lavaca.

Magnolia Beach.- The wells visited in this area range in depth from 150 to 802 feet. A part of the wells have a flow and the water levels in all but one of the nonflowing wells is less than 15 feet beneath the surface. Without exception, the wells that were sampled yield water of poor quality. The chloride content ranges from 690 to 2,350 parts per million; hardness from 140 to 950, and bicarbonate from 290 to 536.

Seadrift.- Of the 26 wells that were visited in the Seadrift area 12 are less than 100 feet in depth, and 13 are between 200 and 365 feet. Ten of the deeper wells have a flow. Most of the wells yield water that is highly mineralized. A few wells less than 100 feet deep in deposits of alluvial and wind-blown sands of Recent age yield water that is comparatively fresh and soft.

Port O'Connor.- The wells visited in this area range in depth from 20 feet to 625 feet, and 18 of them have a flow. Nearly all the wells yield water that is comparatively salty, the water from well 220 being the freshest.

Table of Drillers' Logs, Calhoun County-Continued

	Thickness (feet)	Depth (feet)
--	---------------------	-----------------

Driller's log of well 192-Continued

Red and blue clay - - - - -	35	250
Blue clay - - - - -	45	295
Shell and mud - - - - -	5	300
Wood - - - - -	2	302
Hard blue clay - - - - -	6	308
Red sand - - - - -	17	325

Driller's log of well 194

(J. J. Welder Owner)

Sand - - - - -	60	60
Yellow clay - - - - -	25	85
Sand - - - - -	20	105
Red and yellow clay - -	47	152
Sand - - - - -	8	160
Red and yellow clay - -	52	212
Sand - - - - -	18	230
Soft yellow and brown clay - - - - -	30	260
Blue and yellow clay - -	50	310
Sand and gravel - - - -	17	327

Driller's log of well 208

(P. P. Austin Owner)

Stiff red clay - - - - -	140	140
Sand salt water - - - -	20	160
Fresh water sand and shell -	10	170
Blue clay - - - - -	45	215
Fresh water sand - - - -	15	230
Clay, Artesian sand - - -	256	430
Artesian sand - - - -	70	556

Driller's log of well 214

(P. R. Austin Owner)

Red clay - - - - -	10	10
Fine sand - - - - -	30	40
ough yellow clay - - -	153	183
Fresh water sand - - - -	17	210
No record - - - - -	334	544
Artesian sand - - - -	27	571

Driller's log of well 220

(H. F. Munsch Owner)

Sand with streaks blue clay - - - - -	43	43
Yellow clay - - - - -	70	113
Blue clay with shells -	17	130
Sand - - - - -	20	150

	Thickness (feet)	Depth (feet)
Driller's log of well 266		
Black soil - - - - -	4	4
Sandy clay - - - - -	8	12
Fine grain red sand -	22	34
Sandy clay - - - - -	22	56
Sand - - - - -	43	99
Sandy clay - - - - -	84	133
Sandy clay and shell -	53	225
Sticky shale - - - - -	53	225
Sand - - - - -	23	326
Sticky shale - - - - -	10	334
Sand - - - - -	10	353
Sticky shale - - - - -	?	361
Total depth - - - - -		361
Casing Record: Top to 295 feet; 10-inch blank pipe set in place; 225 to 291 feet, 5½-inch blank pipe; 291 to 320 feet, 5½-inch screen; 320 to 331 feet, 5½-inch blank pipe; 331 to 349½ feet, 5½-inch screen; 349½ to 356½ feet, 5½-inch screen; 356½ to 358 feet, set nipple and valve.		

## Logs of test wells drilled by T. P. A. labor in Calhoun County, Texas

Thickness (feet)	Depth (feet)
<u>Well 300</u>	
Cleared land, no grass or brush, side of county road, $\frac{3}{4}$ miles southeast of Seadrift. Altitude, 10.1 feet.	
Light-gray sand - - - - -	2
Light-gray clay and sand - - -	1
Gray sand and clay - - - - -	11
Red sand - - - - -	14
Gray sand - - - - -	1
Gray clay & shell - - - - -	1
Light-blue clay - - - - -	5
Light-blue clay and shell - - -	2
Blue clay - - - - -	3
Blue clay and shell - - - - -	3
Red clay - - - - -	2
See p. 51 for chemical analyses of samples taken at 17, 25, 35, 45 and 55 feet. Water level 6 ft. below ground level. 36 hours after hole completed.	
February 1, 1940.	

Thickness (feet)	Depth (feet)
<u>Well 301</u>	
Cleared land, no grass or brush, side of county road, $\frac{1}{2}$ miles southeast of Seadrift. Altitude, 6.0 feet.	
Gray sand - - - - -	4
Red sand - - - - -	4
Dark-gray sand - - - - -	3
Light-gray sand - - - - -	2
Red sand - - - - -	4
Sand and boulders - - - - -	2
Red sand - - - - -	7
Hard red clay - - - - -	6
Light-blue clay - - - - -	13
Blue clay and shell - - - - -	4
Caliche boulders - - - - -	2
Fine-grained gray sand - - -	7
See p. 52 for chemical analyses of samples taken at 11, 56 and 58 feet. Water level 5 feet below ground level. 36 hours after hole completed.	
January 31, 1940.	

Thickness (feet)	Depth (feet)
<u>Well 302</u>	
Grass 1 foot high, side of county road, 2 miles east of Seadrift. Altitude, 9.3 feet.	
Dark-colored soil - - - - -	1
Dark-gray sand - - - - -	5
Gray sand - - - - -	3
Red sand - - - - -	13
Red clay - - - - -	3
Hard yellow clay - - - - -	7
Hard gray clay - - - - -	2

Thickness (feet)	Depth (feet)
<u>Well 302--Continued</u>	
Soft red clay - - - - -	10
Caliche and boulders - - -	2
Caliche and sand boulders - - -	5
Water level 14 feet below ground level 36 hours after hole completed.	
January 3, 1940.	

Thickness (feet)	Depth (feet)
<u>Well 303</u>	
Grass 1 foot high, side of county road, $\frac{3}{4}$ miles east of Seadrift. Altitude, 12.2 feet.	
Surface sand - - - - -	1
Clay and sand - - - - -	1
Yellow sand - - - - -	3
Sand and caliche - - - - -	2
Yellow sand - - - - -	1
White sand - - - - -	5
Yellow water sand - - - - -	10
Clay, shell and sand - - - - -	4
Yellow sand and boulders - - -	1
Gray sand - - - - -	2
Blue clay - - - - -	1
Blue clay and shell - - - - -	2
Brown sand - - - - -	1
Brown clay - - - - -	3
Gray clay - - - - -	2
Gray clay and caliche - - - - -	10
Red sand and shell - - - - -	5
Hard caliche - - - - -	1
Sand, caliche and shell - - - - -	1
See p. 52 for chemical analyses of samples collected at 26, 33, 48 and 52 feet. Water level 14 feet below ground level 36 hours after hole completed.	
January 14, 1940.	

Thickness (feet)	Depth (feet)
<u>Well 304</u>	
Grass 1 foot high, side of county road, 3 miles east of Seadrift. Altitude, 3.7 feet.	
Black soil - - - - -	1
Gray sand - - - - -	4
Yellow sand - - - - -	12
Brown sand - - - - -	11
Gray clay - - - - -	2
Sandy gray clay - - - - -	1
Hard blue clay - - - - -	4
Gray clay - - - - -	2
Blue clay - - - - -	2
Brown clay - - - - -	4

Blue and brown clay - - -	6	68
Sandy brown clay - - - - -	5	74
See p. 62 for chemical analyses of samples collected at 13, 29, 40, 55, 62, 69 and 74 feet. Water level 7 feet below ground level, 36 hours after hole completed. April 14, 1940.		

	Thickness (feet)	Depth (feet)
<u>Well 323</u>		
Tall grass, side of county road, 7½ miles west of Seadrift. Altitude, 13.1 feet.		
Light-gray sand - - - - -	5	5
Red clay and sand, wet - - -	7	12
White sand - - - - -	5	17
Gray sand, roots - - - - -	1	18
Dark-gray sand and shell -	5	23
Gray sand - - - - -	13	36
Gray sand and shell - - -	4	40
Brown sand and shell - - -	8	48
Hard blue clay - - - - -	3	51
Blue clay and caliche - - -	4	55
Blue clay - - - - -	5	60
Red clay - - - - -	3	63
Sandy red clay - - - - -	3	72
See p. 62 for chemical analyses of samples collected at 18, 29, 38, 41, 53, 69 and 72 feet. Water level 5 feet below ground level, 40 hours after hole completed. April 21, 1940.		

	Thickness (feet)	Depth (feet)
<u>Well 324</u>		
Tall grass, side of county road, 8½ miles east of Seadrift. Altitude, 9.4 feet.		
Yellow clay and caliche - - -	5	5
Fine-grained yellow sand - - -	6	11
Brown sand - - - - -	25	36
Brown clay - - - - -	2	54
Blue clay - - - - -	6	50
Brown and blue clay - - -	3	58
Blue clay - - - - -	9	67
See p. 62 for chemical analyses of samples collected at 15, 26, and 46 feet. Water level 5 feet below ground level, 45 hours after hole completed.		
April 21, 1940.		
<u>Well 325</u>		
Tall grass, side of county road, 8½ miles east of Seadrift. Altitude, 13.0 feet.		
Gray sand - - - - -	1	1
White sand - - - - -	2	3
Light-gray clay, wet - - - -	4	7

## Partial analyses of water from wells in Calhoun County, Texas

Analyzed at The University of Texas under the direction of Dr. E. P. Schoch, Director of the Bureau of Industrial Chemistry, and E. W. Lohr, Chemist, U. S. Department of the Interior, Geological Survey; by D. F. Riddell, Chemist; and Martin Wieland, Jack Ramsey, and J. H. Raby, Assistant Chemists. Nitrate and fluoride determined by E. J. Lohr. Results are in parts per million. Well numbers correspond to numbers in table of well records.)
