# WATER-LEVEL AND WATER-QUALITY DATA FROM OBSERVATION WELLS IN NORTHEAST TEXAS

## INTRODUCTION

### Purpose and Scope

This report presents basic quantitative and qualitative information concerning ground water which has been collected by the Texas Water Development Board and the U.S. Geological Survey from observation wells in a 20-county area in northeast Texas. The tabulations include current and historical water-level measurements, chemical analyses of the ground water, summaries of ground-water quality by aquifers, and reported amounts of ground water pumped for industrial and municipal purposes. Some of the earlier water-level measurements and water-quality data were collected in cooperation with the U.S. Geological Survey, while the later information was collected from wells in the water level and ground-water quality monitoring networks maintained by the Board in this area. The earlier network was expanded when rapid water-level declines, specifically in Dallas and Tarrant Counties, occurred during the late 1950's and continued into the 1960's. These declines were particularly noticeable in wells developed in the Twin Mountains (Fisher and Rodda, 1966) or Travis Peak Formation.

The report contains introductory material, including a section defining many of the terms appearing in the report; a section on the general geology of the report area as it relates to ground water; tables of basic data; and illustrations portraying conditions reflected by the information in the tables.

Much information dealing with ground water in this area has been published previously by the Board, its predecessor agencies, and the Board in cooperation with the U.S. Geological Survey. Most of those publications are listed in the selected references and are available for examination in the Board's water-resources library.

### Location and Extent of the Area

The report area, shown on the following map, covers approximately 16,270 square miles. It includes all of 20 counties located in north-central and northeast Texas between latitude 31°47' and 33°58'N and longitude 94°44' and 98°04'W. This 20-county area had a 1970 population of 2,657,091 inhabitants with slightly over 75 percent of that population concentrated in Dallas (1,327,321) and Tarrant (716,317) Counties.

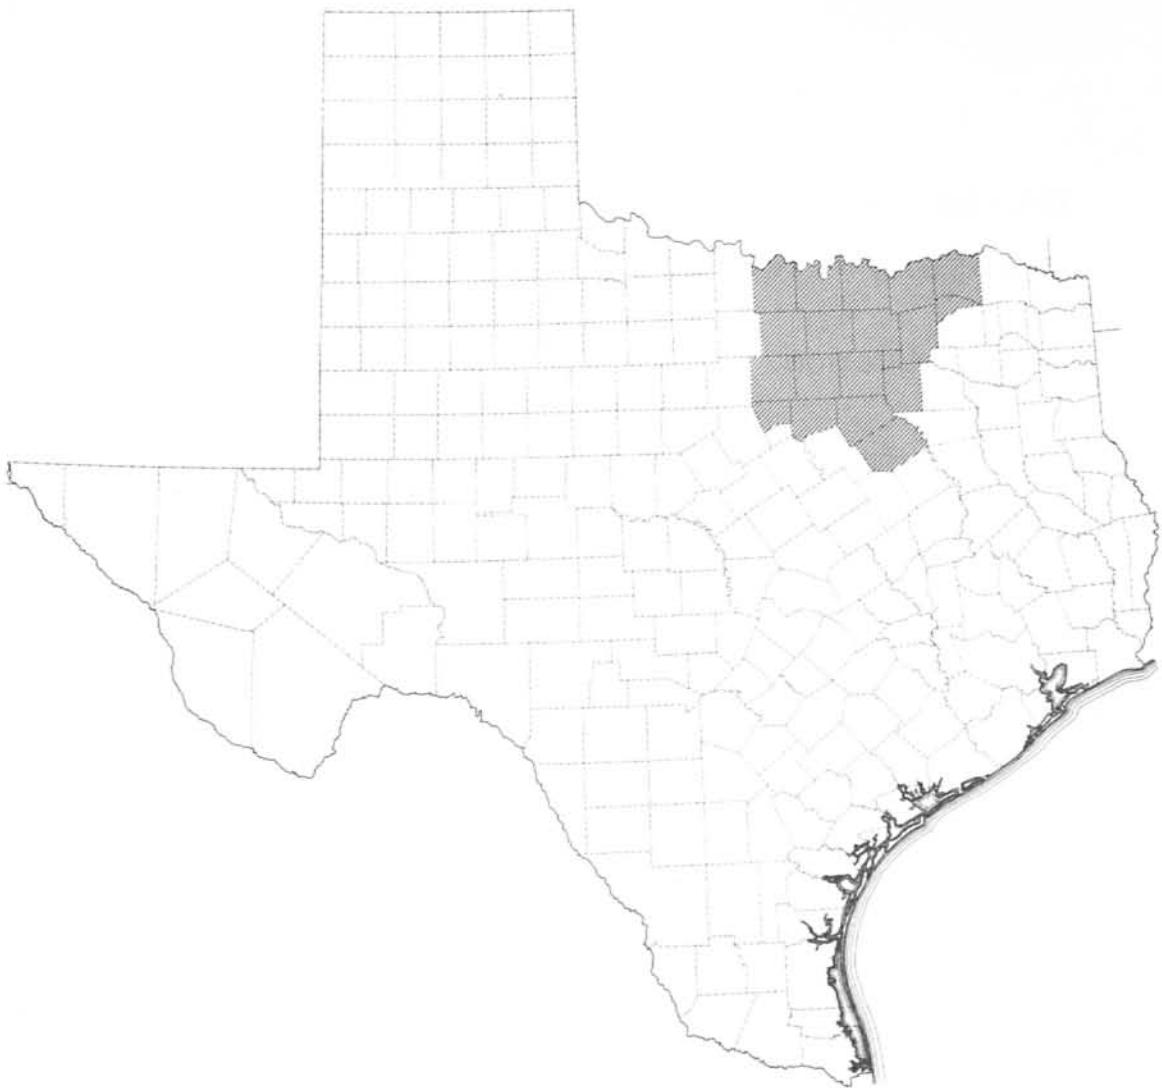

### Personnel

The water-level observation network and the ground water quality monitoring network are the responsibility of personnel in the Ground Water Data and Protection Division, under the general direction of C. R. Baskin, Principal Engineer—Data and Technical Review, and Fred L. Osborne, Jr., director, Ground Water Data and Protection Division. This report was prepared under the supervision of A. Wayne Wyatt, assistant director of the Division, Howard D. Taylor, chief, Water Levels Section. The tabulations of water-level and water-quality data were prepared by the Board's Information Systems and Services Division which is under the direction of David L. Ferguson.

Members of the Water Levels and Ground Water Quality Monitoring Sections who assisted in compiling data for this report are: Dan Corley, Charles Cornelis, Hershel Davidson, John Derton, Stephen Moore, Herbert Spradlin, and Clayton Thornhill.

### Acknowledgements

Special appreciation is expressed to the many individuals, private firms, towns, and cities for their concern and cooperation in allowing their wells in the report area to be measured and water samples taken for

#### Area Covered by This Report

analysis. The cooperation shown by the cities of Dallas, Hurst, and Waxahachie in allowing automatic water-level recorders to be installed on city-owned wells is gratefully acknowledged.

#### Definitions of Terms

Definitions, or brief explanations, of some of the terms used in this report are included in the hope that they will make the data herein more beneficial to the reader. All definitions originated with recognized authorities in the fields of hydrology and geology.

**Acre-foot.**—The volume of water required to cover one acre to a depth of one foot (43,560 cubic feet, or 325,851 gallons).

**Alluvial deposits.**—Sediments deposited by rivers and streams, including flood-plain and stream-terrace deposits.

**Aquifer.**—A water-bearing unit of rock, consolidated or otherwise, which is sufficiently permeable to yield water to wells readily.

**Artesian or confined aquifer.**—An aquifer which is overlain by rock of lower permeability (for example, clay) that confines the water under pressure greater than atmospheric. The water level in an artesian well will rise above the top of the aquifer and may or may not flow.

**Contact.**—The plane or surface where two different kinds of rock or geologic units come together; shown as lines, broken or solid, on geologic maps and cross-sections.

**Dip of rocks or attitude of beds.**—The angle or amount of slope at which a bed is inclined from the horizontal; direction is also usually expressed (for example, one degree, west; or 90 feet per mile, west).

**Discharge.**—Refers to water withdrawn, either naturally or artificially, from the zone of saturation (see definition of ground water).

**Dissolved solids.**—A measure of the total concentration of dissolved material in water. Widely used in evaluating water quality and comparing waters with one another.

**Fault.**—A fracture or fracture zone in rock along which there has been movement or displacement of the two sides relative to one another parallel to the fracture.

**Formation.**—A body of rock that is sufficiently homogeneous or distinctive over fairly large areal distances to be regarded as a mappable unit, generally named from a locality where the formation is typical (for example, Hosston Formation and Woodbine Formation).

**Ground water.**—Refers to water in that area below the land surface in which all the pore spaces and voids are filled with water (called the zone of saturation) and from which wells, springs, and seeps are supplied.

**Hydrograph.**—A graph or line plot showing the fluctuation of the water level in a well over a period of time.

**pH.**—A measure indicating the acidity or alkalinity of water. A pH of 7.0 indicates neutrality, values below 7.0 indicate increasing acidity, and values above 7.0 indicate increasing alkalinity. Other measures are expressed in terms of "phenolphthalein alkalinity," "methyl-orange alkalinity," or its equivalent "total alkalinity."

**Marl.**—A calcareous (limy) clay.

**Measuring point (MP).**—A fixed point at a well from which each water-level measurement in that particular well is calculated.

**Milligrams per liter (mg/l).**—Metric units commonly used in chemical analyses of water to indicate a ratio of dissolved substances, by weight, in a unit volume of water. To illustrate in more common terms, 0.000035 of an ounce of a dissolved substance in 1.05 quarts of water is equivalent to 1 milligram of a dissolved substance in 1 liter of water. For water containing less than 7,000 mg/l dissolved solids, 1 milligram per liter is equivalent to 1 part per million.

**Observation well, current.**—A well from which the Texas Water Development Board is presently collecting and maintaining records either on water-level or water-quality data or both.

**Observation well, historical.**—A well from which the Texas Water Development Board formerly collected and maintained records either on water-level or water-quality data or both.

**Outcrop.**—That part of a rock layer which appears at the land surface. On an areal geologic map, a geological formation or other stratigraphic unit is shown as an area of outcrop where exposed and some times where covered by alluvial deposits (when shown, the contacts below the alluvial deposits are illustrated by dashed or dotted lines).

**Percent sodium.**—A determined value which was previously used to predict the suitability of water for irrigation use. A high value (exceeding 50 percent) found in the water was taken as an indication that, with its repeated use for irrigation, the tilth and permeability of the soil would be adversely affected by the development of excessive sodium in the soil. In 1954, the U.S. Salinity Laboratory proposed replacement of the sodium percentage concept with another determined value called the sodium-adsorption ratio (SAR).

**Potentiometric surface.**—An imaginary surface which everywhere agrees with the static level in an aquifer and to which water in the aquifer will rise under its full head.

**Recharge of ground water.**—The process by which water is added to the zone of saturation (see definition of ground water); when used to designate the quantity added, usually expressed in acre-feet per year or in million gallons per day.

**Residual sodium carbonate (RSC).**—A value used in predicting the suitability of water for irrigation. It indicates the concentration of sodium carbonate in waters after removal of all calcium and magnesium ions by precipitation as carbonates, indicates the effects the waters will have on the soil structure.

**Sodium-adsorption ratio (SAR).**—A determined value used to predict the suitability of water for irrigation use. Repeated use of water for irrigation which has high SAR values (18 or over) may adversely affect the tilth and permeability of a soil by development of excessive sodium in the soil.

**Specific conductance.**—A measure of the ability of a substance to conduct an electrical current, expressed in terms of micromhos per cubic centimeter. The addition

of a very small amount of dissolved minerals to chemically pure water renders the water conductive and, therefore, increases the specific conductance value. This value is often used in the field to give a quick indication of the mineralization of the water obtained from one well or aquifer as compared to that from another well or aquifer.

**Stratigraphy.**—Description of geologic units, such as formations, as to their composition, sequence, and correlation in an area.

**Structure.**—Description of the structural features of rocks in an area (for example, faulting and attitude of beds).

**Total hardness as calcium carbonate ( $\text{CaCO}_3$ ).**—Generally this term indicates the calcium carbonate equivalent of the calcium and magnesium content of the water. Probably the most common significance associated with water hardness is its effect on soap—the “harder” the water the more soap is consumed before a lather will form. Hard water also forms scale on boilers, water heaters, and other plumbing fixtures.

**Transpiration.**—The process by which water, absorbed by plants for building plant tissue, escapes from the plant into the atmosphere.

**Water level.**—The depth below land surface (or distance above land surface if the well flows) to water in a well, usually measured in feet.

**Water level, pumping.**—The level at which water stands in a well when pumping of the well is in progress.

**Water level, static.**—The level at which water stands in a well when no water is being withdrawn from the aquifer.

**Water table.**—The upper surface of a saturated zone except where that surface is confined by a relatively impermeable body of rock.

### Well-Numbering System

The systematic well numbering used in this report was developed by the Texas Water Development Board and is in use statewide. It was designed to identify, facilitate the location of, and avoid duplication of well numbers in present and future studies. The system is based on division of the State into 1-degree quadrangles of latitude and longitude and the repeated division of

these quadrangles into smaller ones as shown in the following diagram.

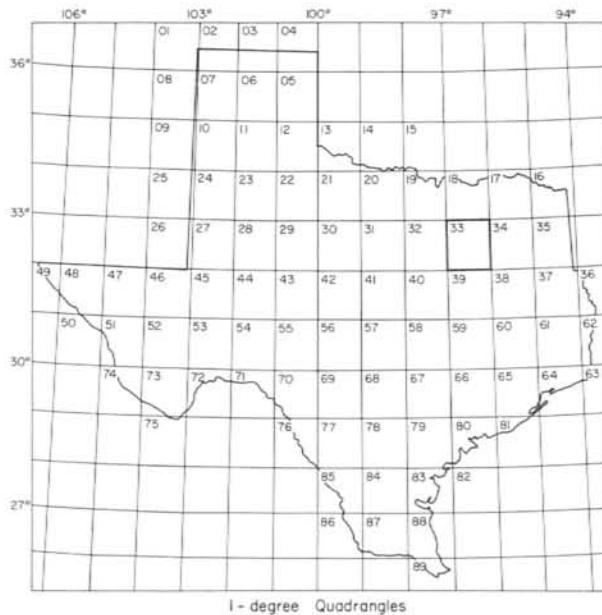

Each 1-degree quadrangle is subdivided into sixty-four  $7\frac{1}{2}$ -minute quadrangles each of which is further subdivided into nine  $2\frac{1}{2}$ -minute quadrangles. Each 1-degree quadrangle in the State has an assigned number. The  $7\frac{1}{2}$ -minute quadrangles are numbered consecutively from left to right, beginning with quadrangle number 01 in the upper left-hand corner of the 1-degree quadrangle. The  $2\frac{1}{2}$ -minute quadrangles within each  $7\frac{1}{2}$ -minute quadrangle are numbered similarly. The wells are numbered consecutively, beginning with 01, within each  $2\frac{1}{2}$ -minute quadrangle. The first two digits of a well number identify the 1-degree quadrangle; the third and fourth digits, the  $7\frac{1}{2}$ -minute quadrangle; the fifth digit, the  $2\frac{1}{2}$ -minute quadrangle; and the sixth and seventh digits identify the particular well in the  $2\frac{1}{2}$ -minute quadrangle.

On the well-location maps in this report, the 1-degree quadrangles are identified with large open-block numbers. The  $7\frac{1}{2}$ -minute quadrangles are numbered in the upper left-hand corner or as near to that position as possible in the cases where a part of the quadrangle falls outside the county. The three-digit numbers near the wells identify the  $2\frac{1}{2}$ -minute quadrangle and the well within that quadrangle.

## GENERAL GEOLOGY AS RELATED TO GROUND WATER

It is not the intent of this report to propose changes in geologic nomenclature or age relationships from those accepted and in use, but rather to relate ground-water data contained herein to the geology of this area in general terms. The nomenclature and stratigraphic relationships used are drawn mostly from sources listed in the references. The general geology of the land surface and the stratigraphic position of the rock units in the report area are shown on the accompanying map and geologic cross section.

In the report area, potable ground water occurs in rocks ranging from the Pennsylvanian System through the Quaternary System. The principal aquifers are beds of the Cretaceous System which are exposed or are in the subsurface over all but the extreme western part of the area. Ground water is also found in Quaternary alluvial gravels, sands, and silty sands along the Brazos, Red, Sulphur, and Trinity Rivers and their main tributaries. Small amounts of ground water are contained in Pennsylvanian and Permian beds in or near their outcrop areas to the west, and also in rocks of

## General Geologic Map of Northeast Texas

Copyright of geological maps in Texas Water Conservation Bulletin 6308, 6307, 6309, and 6310, with some revisions after Geological Atlas of Texas, Department Sheet 1, The University of Texas, Bureau of Economic Geology.

**Generalized Geologic Cross Section  
A-A' Montague to Navarro Counties**

Tertiary age which outcrop along the eastern edge of the area.

### Stratigraphy and Water-Bearing Properties

The Pennsylvanian beds exposed in the report area are composed primarily of shales, sandstones, conglomerates, and some limestones. Ground water occurs primarily in the sandstones and conglomerates. The quality of the ground water is reported to vary within wide limits. These quality variations apparently are not related systematically to depth or location. The yields of wells are small but sufficient for domestic, livestock, and small public supply purposes.

The Permian rocks in Montague County are composed primarily of sandstones and shales. Although many wells are developed in these beds, they have small yields and are used mostly for livestock and domestic purposes. As in the case with the Pennsylvanian, Permian ground-water quality reportedly varies within wide limits with no apparent systematic relationship of the quality variations to depth or location.

Ground water occurs throughout beds of the Cretaceous System from the Trinity Group (oldest) in the western part of the report area to the Navarro Group (youngest) in the eastern part. The principal aquifers are in the Trinity Group of the lower Cretaceous and the Woodbine Group of the upper Cretaceous. The discussion of the geology will be confined almost entirely to these two groups, beginning with the oldest.

The Trinity Group forms the basal section of Cretaceous rocks in the area. It outcrops primarily in Hood, Parker, Wise, Montague, and western Cooke Counties. In ascending order, the Twin Mountains Formation, the Glen Rose Formation, and the Paluxy Formation are divisions of the Trinity outcrop in Hood, Parker, and southern Wise Counties. Northward from central Wise County, limestones of the Glen Rose, which delineate the sands of the overlying Paluxy from those of the underlying Twin Mountains in the area to the south, are absent. In this area a predominantly clay unit is partially equivalent to the Glen Rose and an upper sand unit is partially equivalent to the Paluxy. The lower sands (Twin Mountains) can be traced northward to the vicinity of the Red River. Convenient division of the Trinity into the three subdivisions found to the south cannot be done locally and is not apparent on the outcrop. The name Antlers Formation has been proposed to refer to all sand sequences below the Walnut Formation and above the base of the Cretaceous System (including all Trinity Group rocks) in the outcrop area of northern Wise, Montague, and western Cooke

Counties. The Trinity beds in this area are also known as the Western or upper Cross Timbers sands, Trinity sands undifferentiated, Trinity sands, and Antlers sands.

The Twin Mountains Formation consists chiefly of sands, silty clays, and siliceous conglomerates. It commonly goes by the name "lower Trinity sands" and also is referred to as the Travis Peak Formation by many in the area. However, it is a distinctly different facies from that of the Travis Peak found to the southwest of the report area along the northeast side of the Llano Uplift. In that area, the Travis Peak is primarily made up of conglomerates of pebble and cobble-size limestone and dolomite, calcareous sands and silts, and impure limestones. In the report area, a middle clay unit in the Twin Mountains facies is probably correlative with clay and limestone intervals of the subsurface basinal Pearsall and Sligo Formations found southeastward from the outcrop. Basinal sequences of Hensell and Hosston sands in the McClellan County area to the south are probably correlative with the upper and lower sand units in the Twin Mountains outcrop. The Twin Mountains contains large amounts of ground water throughout the report area, with larger yields coming from thicker sections downdip from the outcrop. Other than having a somewhat high dissolved-solids content, the quality of the ground water generally is suitable for most purposes.

The Glen Rose Formation is composed primarily of marly limestone, marl, shale, some sand, and anhydrite. It contains small amounts of ground water. However, the overlying Paluxy sands and those of the underlying Twin Mountains contain much more ground water of better quality, so that the Glen Rose is not significant as a water-bearing unit in this area.

The Paluxy Formation consists primarily of fine cross-bedded sands, shaly sands, and some sandy limestones. The Paluxy throughout its extent in the report area contains substantial amounts of ground water that is of suitable quality for most uses.

The following table sets out correlations of the Trinity Group and shows nomenclature and stratigraphic relationships in localities in central and northern Texas. The localities shown apply generally in the report area as follows: (1) "North-Central Texas subsurface, eastern part"—southeastern part of the report area, including Navarro, southern Ellis, and southern Kaufman Counties; (2) "North-Central Texas outcrop and subcrop"—central and southern parts, including Hood, Johnson, northern Ellis, Dallas, northern Kaufman, Rockwall, Tarrant, Parker, southern Wise, southern Denton, and Collin Counties; and (3) "North Texas (north of Decatur)"—northern part, including Montague, Cooke, Grayson, northern Wise, and northern Denton

Nomenclature and Stratigraphic Position of Trinity Group Rocks in Some Localities in Central and Northern Texas  
 (Adapted from Fisher and Rodda, 1966)

GROUP	FORMATION NAMES AND LOCALITIES				
	NORTH-CENTRAL TEXAS SUBSURFACE, EASTERN PART	NORTH-CENTRAL TEXAS OUTCROP AND SUBCROP	CENTRAL TEXAS (NORTHEAST SIDE OF THE LLANO UPLIFT)	NORTH TEXAS (NORTH OF DECATUR)	
TRINITY	Glen Rose Formation	Paluxy Formation		Paluxy Formation	upper unit
		Glen Rose Formation		Glen Rose Formation	middle unit
	Hensell Formation	Twin Mountains Formation	upper unit	Travis Peak Formation	Antlers Formation
	Pearsall Formation		middle unit		
	Sligo Limestone		lower unit		
	Hosston Formation				lower unit

Counties. The Central Texas locality is southwest of the report area and includes southern Brown, western Mills, and western Lampasas Counties.

In Trinity Group rocks, fresh to slightly saline ground water (3,000 mg/l or less total dissolved solids) is found as far downdip from the outcrop areas as Navarro, Kaufman, northern Hunt, northern Delta, southern Lamar, and middle Red River Counties.

The Woodbine Group outcrops primarily through eastern Johnson, Tarrant, Denton, and Cooke Counties as well as western and northern Grayson County and extreme northwestern Fannin County. It consists of crossbedded, ferruginous sand, sandy clay, and shale and contains lignite and gypsum in the upper part. The thicker sands are generally in the lower part and are lenticular in nature. In the Tarrant County area, the Woodbine is divided into the Lewisville and Dexter Members. In this area and southward into Johnson County, lignite and gypsum beds in the upper part of the Woodbine cause the ground water to be more highly mineralized than ground water in the lower part of the Woodbine. Northward from Tarrant County the Woodbine thickens and is not readily divided into recognizable units. Eastward from Grayson County the clay content increases and sands decrease so that the Woodbine ceases to be an aquifer in parts of Lamar and Red River Counties.

Ground water is present in the Woodbine in substantial quantities throughout most of the central part of the report area. Although typically high in iron content, the water is suitable for many purposes. Fresh to slightly saline ground water is found as far downdip from the outcrop as western Navarro, Kaufman, Hunt, and northwestern Lamar Counties.

Other Cretaceous System water-bearing units are the Blossom Sand of the Austin Group and the Nacatoch Sand of the Navarro Group. The Blossom Sand consists of unconsolidated, glauconitic, ferruginous, fine- to medium-grained sands interbedded with sandy and chalky marl. The outcrop forms the land surface eastward from central Fannin through central Lamar Counties. In Red River County, the Blossom is largely covered by alluvial terrace gravels. The Blossom Sand contains relatively small amounts of ground water that is generally of suitable quality for most uses except irrigation. The Nacatoch Sand forms a narrow outcrop through central Navarro, Kaufman, southeastern Hunt, southern Delta, and southern Red River Counties. It consists of unconsolidated, massive, glauconitic, calcareous sand and marl. The sands tend to be lenticular with the more persistent ones found in the upper part. The lower Nacatoch is predominantly marl in the eastern

outcrop area in Red River County; however, the proportion of marl decreases westward. The Nacatoch contains small amounts of ground water which tends to deteriorate in quality over fairly short distances downdip. The better quality water is suitable for most uses except irrigation.

The remaining Cretaceous System rocks are the Washita, Fredericksburg, Eagle Ford, Austin, Taylor, and Navarro Groups consisting of clays, marls, limestones, chalks, and shales which, in general, are not conducive to the capture or storage of ground water. The minor amounts of usable ground water in these formations are restricted to the outcrop areas.

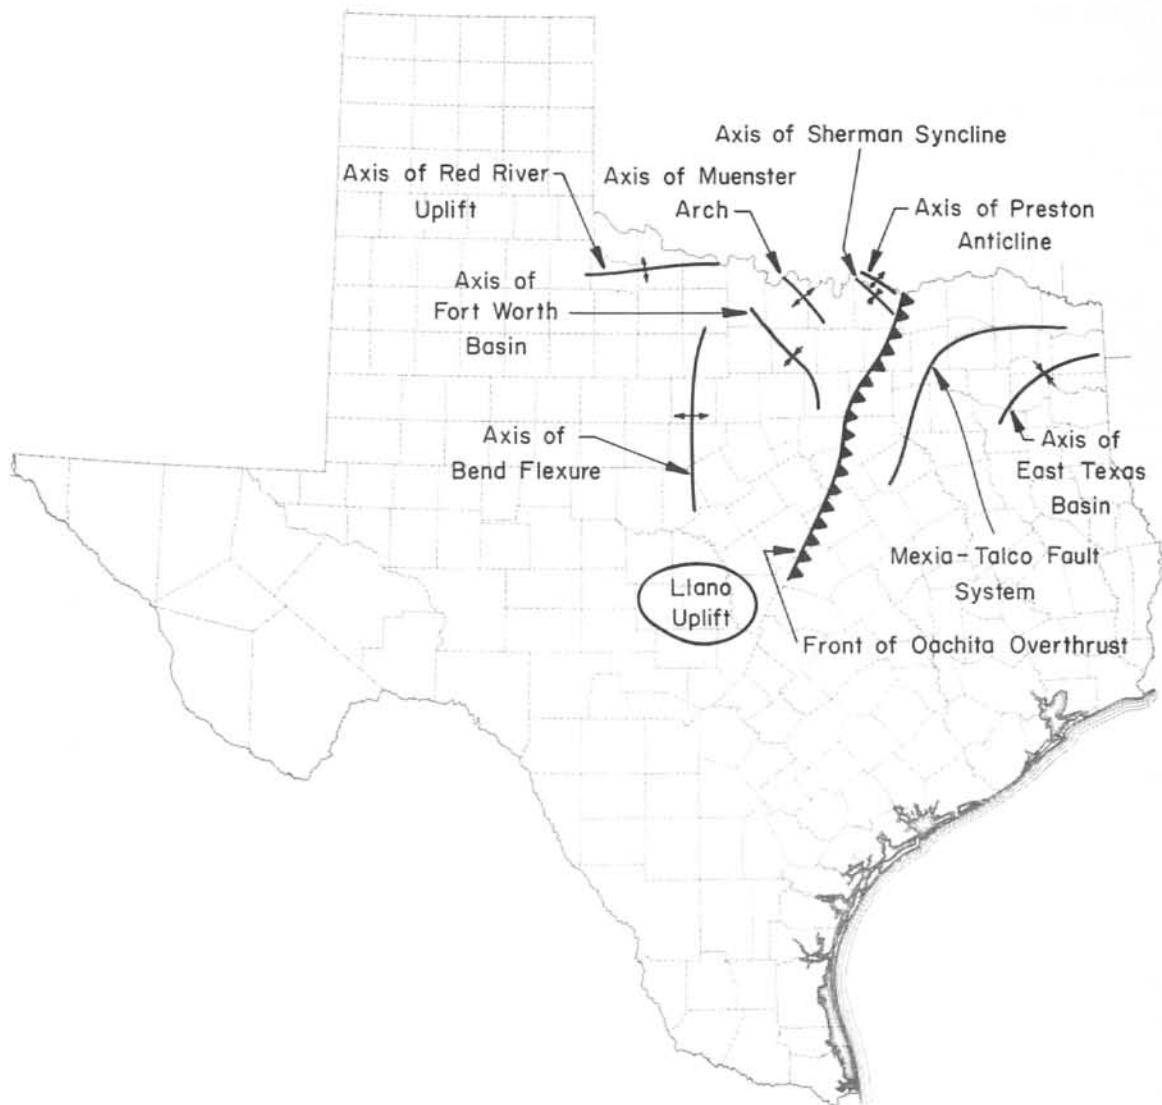

Rocks of the Tertiary System are located in the southeastern and extreme eastern parts of the report area. The Midway Group is composed primarily of silty clay, silt, calcareous and glauconitic sandstone, and sandy limestone. Occurrence of usable ground water in the Midway is erratic and restricted to the outcrop. The Wilcox Group consists of fine sand and silt and contains small amounts of ground water.

Quaternary System alluvial deposits, consisting of sand, clay, silt, and gravel, are found in the floodplains of the Brazos, Red, Sulphur, and Trinity Rivers and along their main tributaries. Quaternary deposits also occur as terraces adjacent to and at slightly higher elevations than the present floodplains of many of these drainage systems. The quantity of ground water in these deposits varies from fairly substantial amounts in areas with thick porous beds, high water levels, and favorable recharge conditions, such as along the Red River in Fannin, Lamar, and Red River Counties, to minor amounts where the beds are thin and conditions for recharge are poor. The quality of the water is generally satisfactory for most uses although it is usually hard and relatively high in silica.

## Structure

Pennsylvanian and Permian rocks in the outcrop dip westward and northwestward at about 40 feet per mile. Permian beds in the report area probably extend not much farther eastward than Montague County. The Pennsylvanian sediments, which underlie the Cretaceous rocks in most of the remaining area, thicken from the outcrop eastward into the deeply buried Fort Worth basin.

The Cretaceous System forms a southeastward-thickening wedge extending across the area into a structural feature known as the East Texas basin. Thickness of these rocks ranges from zero in the

**Major Structural Features From the Llano Uplift  
North and Northeastward to the Red River**

west to nearly 7,500 feet in the southeast. Regional dip is east and southeast at rates of about 15 to 40 feet per mile. The dip rate increases to as much as 300 feet per mile on the flank of a southeastward-plunging ridge called the Preston anticline. This anticline and an associated trough immediately to the south called the Sherman syncline have caused deflection in the regional outcrop pattern as shown on the geologic map.

Tertiary System beds dip regionally southeastward from the Mexia-Talco fault system, which extends in a northerly direction along the eastern margin of the report area, at a rate of about 100 feet per mile. Deviations from this dip rate occur locally due to faulting. These beds attain a thickness in excess of 1,000 feet in Navarro County.

Quaternary deposits occur along the floodplains of the Brazos, Red, Sulphur, and Trinity Rivers and many of their main tributaries. Terraces, which represent remnants of older floodplain deposits of these drainage systems, occur at higher elevations along some of the rivers, particularly the Red River. Alluvial deposits are reported to be as thick as 60 feet in Grayson County. Generally, the alluvial deposits are irregular in thickness and areal extent. Regional slope of these deposits is probably less than 5 feet per mile and generally east and southeast in the direction of the slope of the land surface. Locally, the direction will vary according to the direction of stream or river flow. The following map shows many of the major structural features in and near the report area.

## **WATER LEVEL OBSERVATION NETWORK**

Observation wells have been established and are measured by the Water Development Board in most areas of the State to observe changes in water levels in the principal aquifers. The Board's water level observation network is directed toward the accomplishment of the following objectives: (1) the selection, in all principal aquifers, of observation wells that are spaced to afford sufficient data for preparation of potentiometric-surface and related maps, and graphs which portray changes and fluctuations of ground water; (2) the annual or periodic measurement of water levels in each well in this network at the times when water levels have recovered from periods of peak water demand; (3) the operation of automatic water-level recorders in strategic wells where a continuous record of water-level changes is needed; (4) the evaluation and periodic publication of these water-level data; and (5) the maintenance of the records of these data in the Board's files for examination and use by anyone in need of the information.

## **GROUND WATER QUALITY MONITORING NETWORK**

The Board maintains a network of observation wells for monitoring water quality in the principal aquifers of the State. Some of these wells are also water-level observation wells. It is the desire of the Board to accomplish the following objectives with this network: (1) selection of an adequate number of observation wells properly spaced in all the principal aquifers to be able to obtain sufficient data for preparation of various ground-water quality maps, graphs, and other illustrative and definitive material; (2) periodic sampling of the water in these wells for chemical analysis to detect any changes in the chemical quality of the water, in order to be able to make appropriate recommendations for any action deemed necessary; (3) evaluation and periodic publication of these water-quality data; and (4) maintenance and storage of the records of these data in the Board's files for examination and use by anyone in need of the information.

### **METHODS OF COLLECTING WATER-LEVEL AND WATER-QUALITY DATA**

Water levels in most current observation wells in this report are measured on an annual basis. If possible, wells selected for annual observation purposes should

not be equipped with a pump and should be located a reasonable distance from heavily pumped wells. These conditions cannot always be met; therefore, it becomes necessary to measure water levels in equipped wells and wells in frequent use. In these cases, the water levels are measured after allowance of sufficient time following cessation of pumping for the water levels to recover to static or near-static conditions. In irrigation areas, it is desirable to measure water levels in the winter months when pumping is at a minimum and water levels have recovered to their highest levels.

In this report, water levels are recorded as depth to water in feet below land surface or, in rare instances, distance in feet above land surface (the plus sign before a figure in the "measurement" column the table of water-level measurements indicates a flowing well). The depth to water below land surface is obtained by subtracting the vertical distance between the measuring point on a well and the land surface from the vertical distance between the measuring point and the water level in the well. In flowing wells of small capacity, the distance above land surface may be measured directly with a hand tape; for large-capacity flowing wells the distance is calculated from a pressure reading. The following methods were used to obtain the water-level measurements in this report:

#### **(1) Wetted Steel Tape**

In using this measuring method, a calibrated steel tape is lowered into the well bore until a part, usually about one or two feet, is submerged in the water, and an even foot mark on the tape is held at the measuring point on the well. The depth to water below this measuring point is then calculated by subtracting the amount of wet tape from the foot mark held at the measuring point. Water levels measured with a steel tape are recorded to the nearest one-hundredth of a foot. This method of obtaining water-level measurements is considered the most accurate and is therefore the most commonly used.

#### **(2) Electric Line**

The electric line measuring equipment consists of a hand-operated reel, a current meter, a dry-cell battery for power, and a length of double-conductor insulated wire with electrodes at the lower end. The electric line operates on the principle of a completed electric circuit. When contact is made between the water surface in the well

and the electrodes on the end of the electric line, the circuit is completed and indicated on the current meter at the land surface. Calibrated markings along the electric line provide the means for direct reading of the depth to the water level. This method is used when a measurement with steel tape is not feasible, such as in a well in which water is leaking or flowing into the bore hole above the water level. Water-level measurements obtained by this method are recorded to the nearest tenth of a foot.

(3) Air Line

This method employs the use of a small diameter pipe or tube, such as copper tubing, which is airtight and installed in the annular space between the pump column and the casing in the well. This tube, or air line, should be stabilized and as true vertically as possible. It must extend several feet below the lowest pumping water level in the well, be open at the submerged end, and its length from a reference point on the well to the submerged end must be known. Airtight connections are necessary because air is forced into the tube, and pressure is measured with a gage installed at the surface. The air line device works on the principle that air pressure required to push all the water out of the submerged end of the line equals the pressure exerted by the column of water standing outside the air line. Gages that measure directly in feet of water are available; however, readings of pressure in pounds per square inch may be multiplied by 2.31 for conversion to feet of water. By subtracting the feet of water in the submerged end of the line from the known length of the line, the depth to water can be ascertained. This method is not as accurate as those previously described, but is in fairly wide use in certain applications due to its speed and simplicity. It is also used where deep water levels render the previously described methods impractical, or in a pumping well where a more precise method could not be used due to water turbulence.

(4) Automatic Water-Level Recorder

This method requires that an automatic recording device be installed over a well. A float is suspended in the well and attached to the recording device by a

calibrated metal tape or cable. As the water level rises or falls, the float moves up or down, and this movement is continuously recorded by a stylus on chart paper held on a clock-driven drum in the recorder. The recorders are housed in small metal buildings for protection against vandalism and the elements. Automatic recorders are the best means for obtaining continuous records of any rapid and irregular water-level fluctuations in areas of large ground-water development. The recorders are visited at frequent intervals for maintenance and collection of the water-level charts. Water-level readings taken from the charts are tabulated to the nearest one-hundredth of a foot.

Ground water quality data are obtained through the periodic sampling of water from observation wells for chemical analysis. The water is usually collected in one-quart, plastic, sterilized bottles, preferably after a well has been pumped for some time. Information concerning the identity of the well from which the sample was drawn, date of sample collection, and other data are tabulated, and the sample is forwarded to the State Health Department for, in most cases, a routine chemical analysis. Depending upon the specific information desired, frequency of collection of water samples for analysis may vary from more than once a day to once in several years.

The relatively slow movement of water through the ground affords a very close and lengthy contact of the water with the minerals in the various rocks that make up the earth's crust. These minerals are water-soluble to a greater or lesser degree, causing the ground water to become generally more mineralized as it moves along. The chemical processes are affected by many variables in the environment; wide variations in the chemical makeup of ground water, even within relatively small areas, are encountered. While many properties can be determined by chemical analysis, in most instances determining the concentrations of only the relatively few ions that commonly occur in ground water will convey an adequate picture of the suitability of the water for the usual domestic, municipal, industrial, and irrigation uses.

## FLUCTUATIONS OF WATER LEVELS

The water level in a well is an indication of the water table or piezometric surface of an aquifer in a given area. Changes in the water level from time to time may be caused by one or more factors. Very slight

declines or rises of the water level may be due to climatic changes, tidal forces, or to the withdrawal of ground water from a distant or nearby well. Earthquakes can also cause changes in water levels. Heavy pumping of wells, such as in areas where there is heavy usage of ground water for industrial, irrigation, or municipal purposes, can cause dramatic changes in water levels amounting to hundreds of feet, depending on the aquifer conditions. Generally, ground water is least affected during the winter months by such things as well pumping, evaporation, and transpiration by vegetation. This is reflected by higher, more stable water levels at this time of year. Conversely, water levels are generally lower in the spring, summer, and fall months, reflecting the increase in well pumping, higher evaporation rates, and renewed and continued growth of vegetation.

Long-term declines in water levels reflect decreases in the volume of water stored in an aquifer. Likewise, a long-term rise in water levels would indicate increase in the volume of water stored in an aquifer. When the discharge of ground water from an aquifer is greater than the recharge of water to it, water levels will decline, and when recharge exceeds discharge the water levels will rise.

Undoubtedly, water levels have declined considerably within the report area since the turn of the century. Long-term water-level measurements from scattered wells in Dallas and Tarrant Counties indicate some fairly steep decline rates within the past 20 years. The following seven illustrations show declines and related hydrologic information.

The hydrographs show declines ranging from as little as about 1 foot per year over a 20-year period from 1952-71 in a well in Dallas County, developed in the Woodbine Formation, to slightly under 46 feet per year during a 7-year period from 1951-57 in a well in eastern Tarrant County, developed in the Twin Mountains Formation. Also in eastern Tarrant County, another well reflected a water level decline rate of over 20 feet per year in the Paluxy Formation.

The map showing a generalized estimate of the decline of water levels in the Twin Mountains Formation in Dallas and Tarrant Counties for the period 1954-72 is based on the hydrographs as well as on current and historical water-level data in this area. Also, a map showing the approximate potentiometric surface of the Twin Mountains Formation in 1972 in Dallas, Tarrant, and parts of the surrounding counties is given. Both maps are based on limited data and should be used accordingly.

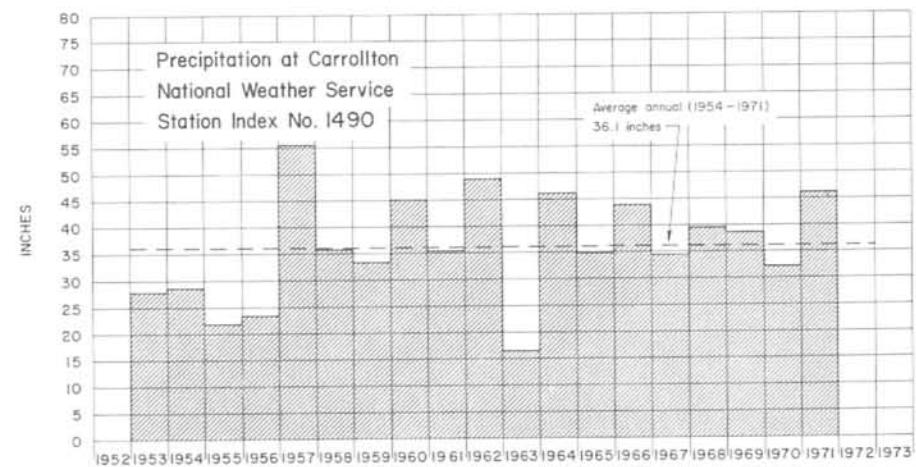

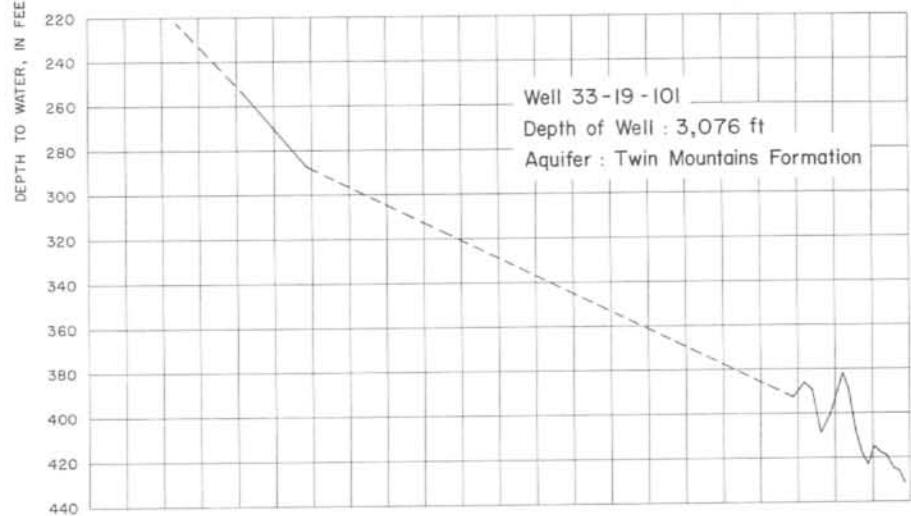

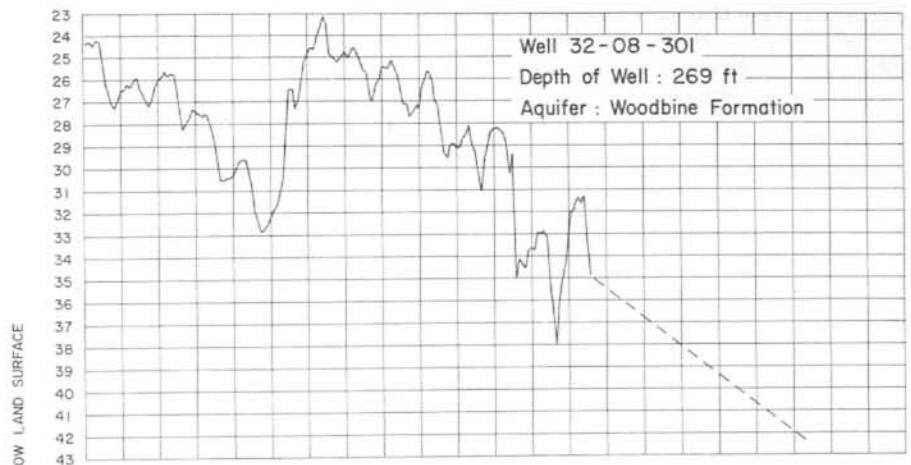

Graphs showing the reported ground-water pumping for municipal and industrial purposes in Dallas and Tarrant Counties for the period from 1955 through 1972 are also shown. In Dallas County the demand for ground water for these purposes appears to have been fairly constant since the late 1950's, while the demand in Tarrant County has increased slightly since the early 1960's.

## PRESENTATION OF DATA

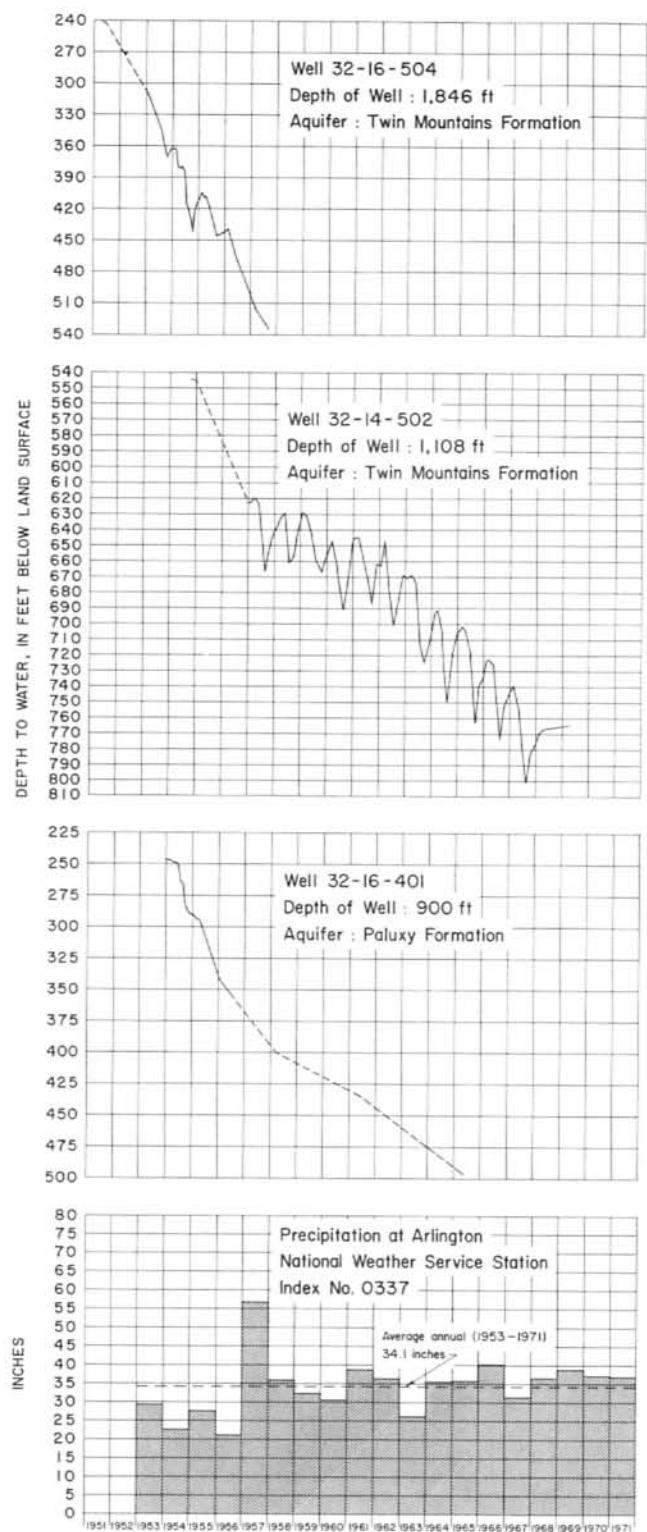

Tabulations of water-level measurements, chemical quality of ground water, and reported ground-water pumping for municipal and industrial purposes are presented in the latter part of this report by county, and the counties are arranged alphabetically. The order in which the information is shown for each county is: (1) a map showing the location of all wells in that county from which the data were collected; (2) a table showing the water-level measurements collected from each well; (3) a table showing the results of chemical analyses of water samples collected from individual wells since 1969 (plus a few older analyses of some of these wells); (4) a table showing a summary of the chemical quality of the ground water in the important aquifers (in some counties) based on available chemical analyses from wells developed in the particular aquifers; and (5) a table of reported municipal and industrial pumping. The following symbols are used for aquifers in the various tables:

SYMBOL	SYSTEM	UNIT
QUATERNARY		
QAL		Alluvium
