## **Executive summary**

In February 2020, the Texas Water Development Board (TWDB) entered into an agreement with the Tarrant Regional Water District to perform a volumetric and sedimentation survey of Lake Bridgeport (Jack and Wise counties, Texas). Surveying was performed using a multi-frequency (208 kHz, 50 kHz, and 12 kHz), sub-bottom profiling depth sounder. Sediment core samples were collected and correlated with sub-bottom acoustic profiles to estimate sediment accumulation thicknesses and sedimentation rates.

Bridgeport Dam, impounding Lake Bridgeport, is located on the West Fork Trinity River in Wise County, approximately four miles west of Bridgeport, Texas. The conservation pool elevation of Lake Bridgeport is 836.0 feet NAVD88. The TWDB collected bathymetric data for Lake Bridgeport between September 29 and October 7, 2020, while daily average water surface elevations ranged between 833.58 and 833.97 feet NAVD88.

**The 2020 TWDB volumetric survey indicates Lake Bridgeport has a total reservoir capacity of 372,183 acre-feet and encompasses 12,338 acres at conservation pool elevation (836.0 feet NAVD88).** The vertical datum of the U.S. Geological Survey gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below the previous datum. Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88. Surveys prior to 2016 estimate total reservoir capacity at elevation 836.0 feet NGVD29 or 835.56 feet NAVD88. Previous capacity estimates include Freese and Nichols studies in 1959 of 386,420 acre-feet, in 1968 of 386,559 acre-feet, and in 1988 of 374,836 acre-feet. Previous TWDB capacity estimates include a re-calculated 2000 survey estimate of 369,251 acre-feet, and a re-calculated 2010 survey estimate of 363,271 acre-feet. At elevation 836.0 feet NGVD29 equivalent to 835.56 feet NAVD88, the 2020 TWDB survey indicates a capacity of 366,782 acre-feet. Because of differences in past and present survey methodologies, direct comparison of volumetric surveys to others to estimate loss of area and capacity can be unreliable. Information from past surveys is presented here for informational purposes only.

**The 2020 TWDB sedimentation survey measured 23,439 acre-feet of sediment below conservation pool elevation 836.0 feet NAVD88.** The sedimentation survey indicates sediment accumulation is greatest in the river channels with heavy accumulation in the submerged floodplains of the main channel and tributaries. The TWDB recommends that a similar methodology be used to resurvey Lake Bridgeport in 10 years or after a major high flow event.

## **Introduction**

The Hydrographic Survey Program of the Texas Water Development Board (TWDB) was authorized by the 72nd Texas State Legislature in 1991. Texas Water Code Section 15.804 authorizes the TWDB to perform surveys to determine reservoir storage capacity, sedimentation levels, rates of sedimentation, and projected water supply availability.

In February 2020, the TWDB entered into an agreement with the Tarrant Regional Water District (TRWD), to perform a volumetric and sedimentation survey of Lake Bridgeport (Texas Water Development Board, 2020). This report provides an overview of the survey methods, analysis techniques, and associated results. Also included are the following contract deliverables: (1) an elevation-area-capacity table of the reservoir acceptable to the Texas Commission on Environmental Quality (Appendices I and J), (2) a bottom contour map (Figure 6), (3) a shaded relief plot of the reservoir bottom (Figure 4), and (4) an estimate of sediment accumulation and location (Figure 10).

## **Lake Bridgeport general information**

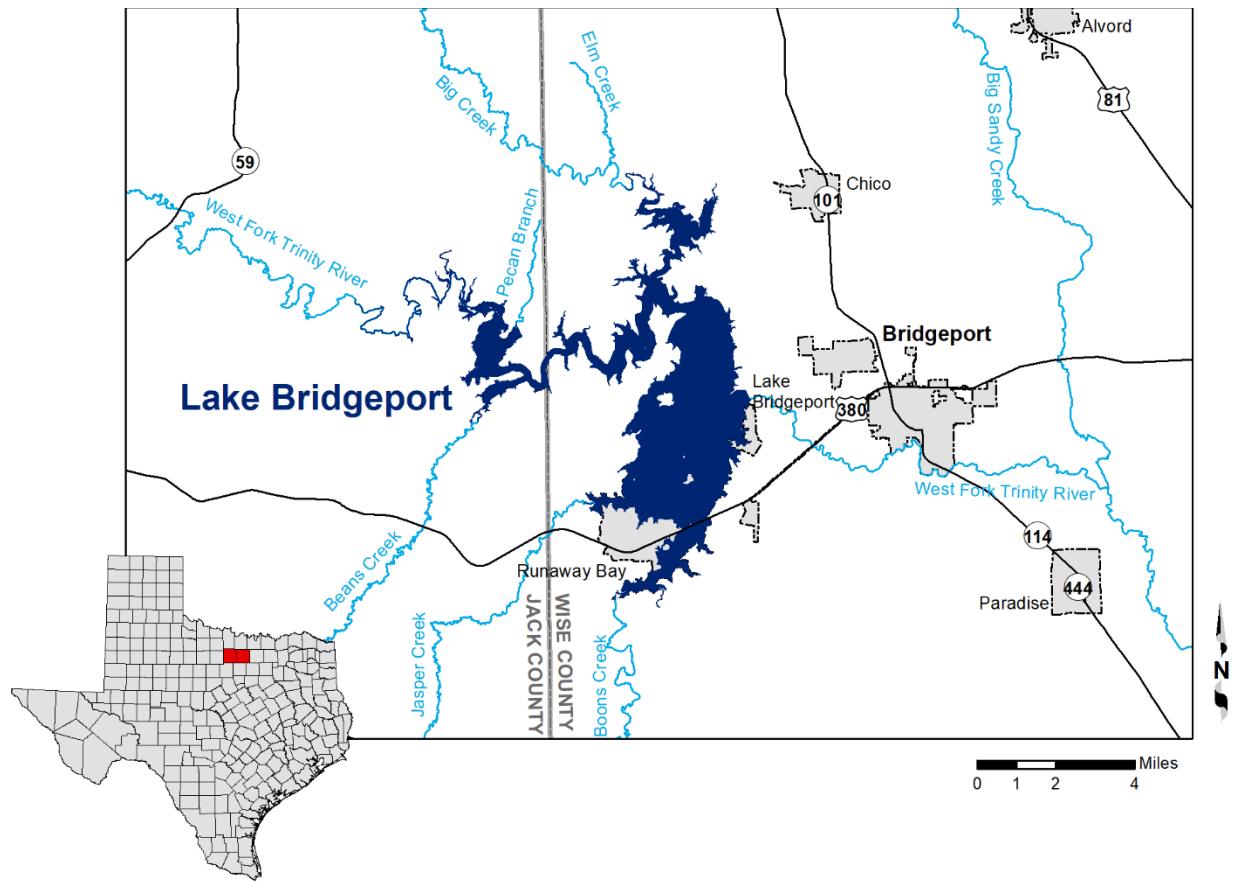

Bridgeport Dam, impounding Lake Bridgeport, is located on the West Fork Trinity River in Jack and Wise counties, approximately four miles west of Bridgeport, Texas (Figure 1). The lake was authorized by the State Board of Water Engineers by Water Rights Permit No. 1074 (Application No. 1145) to the Tarrant County Water Control and Improvement District No. 1 (TRWD) on May 1, 1928. Construction of the original Bridgeport Dam began on January 23, 1930, and the dam was completed on December 15, 1931. Deliberate impoundment of water began on April 1, 1932 (Texas Water Development Board, 1973). The design engineer for the project was Hawley, Freese and Nichols. The general contractor was McKenzie and Uvalde Construction Companies. Lake Bridgeport Dam was initially constructed to an elevation of 863.0 feet above mean sea level with a normal pool elevation of 826.0 feet above mean sea level. Two additional embankments were constructed to the southwest: the Saddle Gap Levee and the Berkshire Levee. These levees were also constructed to an elevation of 863.0 feet.

In the early 1970s modifications were made at Lake Bridgeport to increase storage and discharge capacities. The main dam, Berkshire Levee, and Saddle Gap Levee were raised to elevation of 874 feet. The original four-bay spillway was sealed and covered when the dam embankment was raised, though the original structure can still be seen from the lake. A new spillway was constructed approximately 3,000 feet north of the main dam. The new spillway is controlled by 8 vertical gates with a top elevation of 841.52 feet when the gates are in the closed

position. New outlet works were also added as part of the modification. A 60-inch diameter steel pipe with entrance elbow is located in part of the spillway wall. The new invert elevation of the elbow is 810.00 feet and is controlled by a slide gate at the discharge end of the pipe. A 700-foot-wide natural ground emergency spillway with a crest elevation of 866.00 feet is located in the right overbank of the service spillway discharge channel, just downstream of the spillway. With modifications to the dam and spillway complete, elevation 836.00 feet NGVD29 became the new conservation pool level beginning in Water Year 1973. Beginning on October 1, 2016, the conservation pool elevation was changed to 836.00 feet NAVD88 (U.S. Geological Survey, 2021; C. Ottman, written commun(s.), 2021). Maximum design water surface may reach to 871.22 feet, while the top of flood easement, used for temporary impoundment of flood water, is at elevation of 851.00 feet. Additional pertinent data about Bridgeport Dam and Lake Bridgeport can be found in Table 1.

Lake Bridgeport is owned by the TRWD and is operated in conjunction with Eagle Mountain Lake (also owned by TRWD) and Lake Worth (owned by the City of Fort Worth) as a system. Authorized usage of the impoundment includes municipal, irrigation, mining, industrial, transport (to Eagle Mountain Lake) and recreational purposes. The TRWD provides “raw water” to more than 30 wholesale customers in 11 North Texas counties (Tarrant Regional Water District, 2021).

Water rights for Lake Bridgeport have been appropriated to the TRWD through Certificate of Adjudication No. 08-3808 and Amendment to Certificate of Adjudication Nos. 08-3808A, 08-3808B, and 08-3808C (Texas Commission on Environmental Quality, 2021). The complete certificates are on file at the Texas Commission on Environmental Quality (TCEQ).

<sup>a</sup>. Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (C. Ottman, written commun(s.), 2021).

<sup>b</sup>. Usable conservation storage equals total capacity at conservation pool elevation minus dead pool capacity. Dead pool refers to water that cannot be drained by gravity through a dam's outlet works.

# Volumetric and sedimentation survey of Lake Bridgeport

## Datum

The vertical datum used during this survey is North American Vertical Datum 1988 (NAVD88). This datum is utilized by the United States Geological Survey (USGS) for the reservoir elevation gage *USGS 08043000 Bridgeport Res abv Bridgeport, TX* (U.S. Geological Survey, 2021). This datum became effective October 1, 2016, and is 0.44 feet below the previous datum National Geodetic Vertical Datum 1929 (NGVD29) (U.S. Geological Survey, 2021). Prior to 2016, conservation pool elevation was 836.0 feet National Geodetic Vertical Datum 1929 (NGVD29). Conservation pool elevation is now 836.0 feet NAVD88 (C. Ottman, written commun(s), 2021). Elevations herein are reported in feet relative to the NAVD88 datum. Volume and area calculations in this report are referenced to water levels reported by the USGS gage. The horizontal datum used for this report is North American Datum 1983 (NAD83), and the horizontal coordinate system is State Plane Texas North Central Zone (feet).

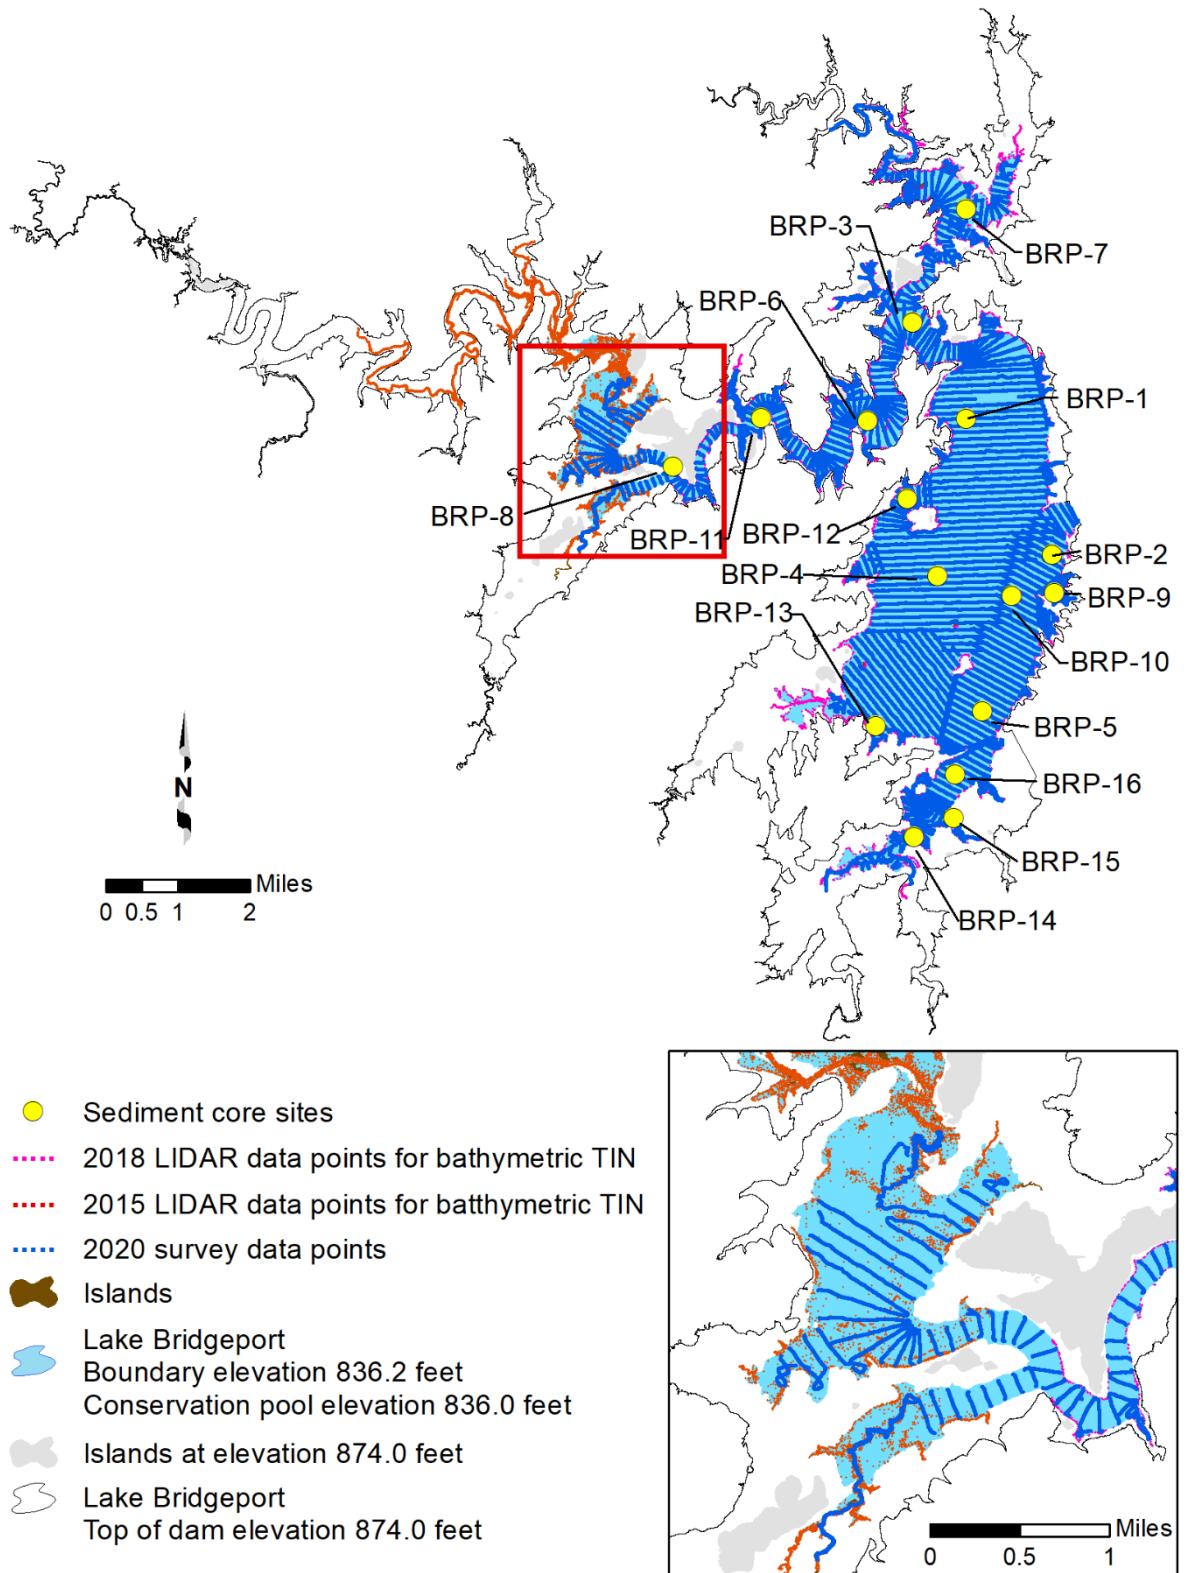

## TWDB bathymetric and sedimentation data collection

The TWDB collected bathymetric data for Lake Bridgeport between September 29 and October 7, 2020, while daily water surface elevations ranged from 833.58 and 833.97 feet NAVD88. For data collection, the TWDB used a Specialty Devices, Inc. (SDI), single-beam, multi-frequency (208 kHz, 50 kHz, and 12 kHz) sub-bottom profiling depth sounder integrated with differential global positioning system (DGPS) equipment. Data were collected along pre-planned survey lines oriented perpendicular to the assumed location of the original river channels and spaced approximately 500 feet apart. Many of the same survey lines also were used by the TWDB for the *Volumetric Survey of Lake Bridgeport, April 2000 Survey* (Texas Water Development Board, 2001) and the *Volumetric and Sedimentation Survey of Lake Bridgeport, October-December 2010 Survey* (Texas Water Development Board, 2012). The depth sounder was calibrated daily using a velocity profiler to measure the speed of sound in the water column and a weighted tape or stadia rod for depth reading verification. Each speed of sound profile, or velocity cast, is saved for further data processing. Figure 2 shows the data collection locations for the 2020 TWDB survey.

All sounding data were collected and reviewed before sediment core sampling sites were selected. Sediment core samples are collected throughout the reservoir to assist with interpretation of the sub-bottom acoustic profiles. After analyzing the sounding data, the TWDB

selected 16 locations to collect sediment core samples (Figure 2). Sediment cores were collected on April 21-22, 2021, with a custom-coring boat and an SDI VibeCore system.

Sediment cores are collected in 3-inch diameter aluminum tubes. A sediment core extends from the current reservoir-bottom surface, through the accumulated sediment, and into the pre-impoundment surface. After the sample is retrieved, the core tube is cut to the level of the sediment core. The tube is capped, labeled, and transported to TWDB headquarters for further analysis.

**Figure 2.** 2020 TWDB sounding data (blue dots), sediment coring locations (yellow circles), 2015 LIDAR data for bathymetric model (red dots), and 2018 LIDAR data for bathymetric model (pink dots).

## **Data processing**

### **Model boundary**

The bathymetric model boundary of the reservoir was digitized from aerial photographs, also known as digital orthophoto quarter-quadrangle images (DOQQs), obtained through the Texas Imagery Service. The Texas Natural Resources Information System manages the Texas Imagery Service, allowing public organizations in the State of Texas to access high resolution imagery as a service using Environmental Systems Research Institute's ArcGIS software (Texas Natural Resources Information System, 2020a, Texas Natural Resources Information System, 2020b). DOQQs photographed on January 28, 2017, while the daily average water surface elevation measured 836.22 feet, were used to digitize a model boundary at the land-water interface. For modeling purposes, the boundary was assigned an elevation of 836.2 feet.

The upper reaches (Beans Creek and the West Fork Trinity River area) of the bathymetric model boundary of the reservoir were generated with Light Detection and Ranging (LIDAR) data available from the Texas Natural Resource Information System (TNRIS). LIDAR data were acquired between January 4 and January 16, 2015, and March 11-12, 2015, while the daily average water surface elevation of the reservoir measured between 811.79 and 811.91 feet and 811.97 and 811.98 feet. The topographic model boundary of the reservoir was generated with LIDAR data available from the Texas Natural Resource Information System (TNRIS). For the area of the reservoir downstream of Beans Creek, LIDAR data acquired between February 1 and May 27, 2018, while the daily average water surface elevation of the reservoir measured between 831.51 feet and 835.35 feet were used (Figure 2). All LIDAR data were imported into an Environmental Systems Research Institute's ArcGIS file geodatabase. The LIDAR data .las files were imported into an LAS Dataset and the dataset was converted to a raster using a cell size of 1.0 meter by 1.0 meter. The horizontal datum of the LIDAR data is North American Datum 1983 (NAD83; meters) and the projection is Universal Transverse Mercator (UTM) Zone 14. The vertical datum is North American Vertical Datum 1988 (NAVD88; meters). A contour representing the top of dam elevation of 266.395 meters NAVD88, equivalent to 874.0 feet NAVD88 was extracted from the raster. The topographic model contour was edited to close the contour across the dam and remove other artifacts. Horizontal coordinate transformations to NAD83 State Plane Texas North Central Zone (feet) coordinates were applied using the ArcGIS Project tool.

## **LIDAR data points**

To utilize the LIDAR data in the reservoir topographic model, the LIDAR data .las files were converted to a multipoint feature class in an Environmental Systems Research Institute's ArcGIS file geodatabase filtered to include only data classified as ground points. A topographical model of the data was generated. The ArcGIS tool Terrain to Points was used to extract points from the Terrain, or topographical model of the reservoir. The Terrain was created using the z-tolerance Pyramid Type. Points were extracted from the terrain at the z-tolerance level of 0.5 meters. New attribute fields were added to convert the elevations from meters to feet NAVD88 for compatibility with the bathymetric survey data. LIDAR data outside of the 874.00-foot contour were deleted and the feature class projected to NAD83 State Plane Texas Central Zone (feet). Where 2015 LIDAR data points and survey data points did not agree, LIDAR data were removed from the model.

## **Triangulated Irregular Network model**

Following completion of data collection, the raw data files collected by the TWDB were edited to remove data anomalies. The current bottom surface of the reservoir is automatically determined by the data acquisition software. Hydropick software, developed by TWDB staff, was used to display, interpret, and edit the multi-frequency data by manually removing data anomalies in the current bottom surface and to manually edit the pre-impoundment surfaces. The speed of sound profiles, also known as velocity casts, were used to further refine the measured depths. For each location velocity casts are collected, the harmonic mean sound speed of all the casts is calculated. From this, depths collected using one average speed of sound are corrected with an overall optimum speed of sound for each specific depth (Specialty Devices, Inc., 2018).

All data were exported into a single file, including the current reservoir bottom surface, pre-impoundment surface, and sediment thickness at each sounding location. The water surface elevation at the time of each sounding was used to convert each sounding depth to a corresponding reservoir-bottom elevation. This survey point dataset was then preconditioned by inserting a uniform grid of artificial survey points between the actual survey lines. Bathymetric elevations at these artificial points were determined using an anisotropic spatial interpolation algorithm described in the next section. This technique creates a high resolution, uniform grid of interpolated bathymetric elevation points throughout a majority of the reservoir (McEwen *et al.* 2011a). The resulting point file was used in conjunction with sounding and boundary data to create volumetric and sediment Triangulated Irregular Network (TIN) models utilizing the 3D

Analyst Extension of ArcGIS. The 3D Analyst algorithm uses Delaunay's criteria for triangulation to create a grid composed of triangles from non-uniformly spaced points, including the boundary vertices (Environmental Systems Research Institute, 1995).

### **Spatial interpolation of reservoir bathymetry**

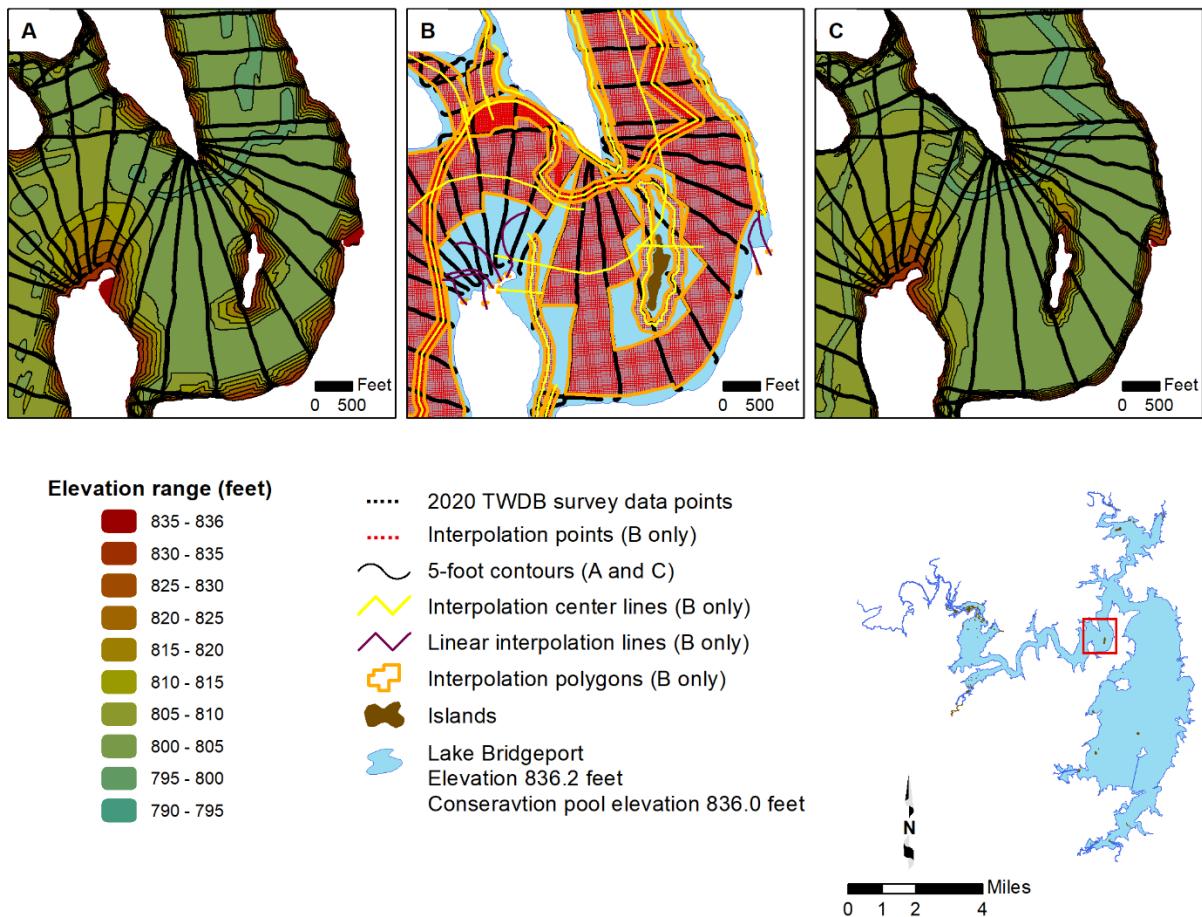

Isotropic spatial interpolation techniques such as the Delaunay triangulation used by the 3D Analyst extension of ArcGIS are, in many instances, unable to suitably interpolate bathymetry between survey lines common to reservoir surveys. Reservoirs and stream channels are anisotropic morphological features where bathymetry at any particular location is more similar to upstream and downstream locations than to transverse locations. Interpolation schemes that do not consider this anisotropy lead to the creation of several types of artifacts in the final representation of the reservoir bottom surface and hence to errors in volume. These artifacts may include artificially curved contour lines extending into the reservoir where the reservoir walls are steep or the reservoir is relatively narrow, intermittent representation of submerged stream channel connectivity, and oscillations of contour lines in between survey lines. These artifacts reduce the accuracy of the resulting volumetric and sediment TIN models in areas between actual survey data.

To improve the accuracy of bathymetric representation between survey lines, the TWDB developed various anisotropic spatial interpolation techniques. Generally, the directionality of interpolation at different locations of a reservoir can be determined from external data sources. A basic assumption is that the reservoir profile in the vicinity of a particular location has upstream and downstream similarity. In addition, the sinuosity and directionality of submerged stream channels can be determined by directly examining the survey data, or more robustly by examining scanned USGS 7.5-minute quadrangle maps (DRGs), hypsography files (the vector format of USGS 7.5-minute quadrangle map contours), and historical aerial photographs, when available. Using the survey data, polygons are created to partition the reservoir into segments with centerlines defining the directionality of interpolation within each segment. Using the interpolation definition files and survey data, the current reservoir-bottom elevation, pre-impoundment elevation, and sediment thickness are calculated for each point in the high-resolution uniform grid of artificial survey points. The reservoir boundary, artificial survey points grid, and survey data points are used to create volumetric and sediment TIN models representing reservoir bathymetry and sediment accumulation throughout the reservoir. Specific

details of this interpolation technique can be found in the HydroTools manual (McEwen and others, 2011a) and in McEwen and others (2011b).

In areas inaccessible to survey data collection, such as small coves and shallow upstream areas of the reservoir, linear interpolation is used for volumetric and sediment accumulation estimations (McEwen and others, 2011a). Although LIDAR was utilized, linear interpolation was necessary to accurately model features in the areas between survey data and LIDAR data. Linear interpolation results in improved elevation-capacity and elevation-area calculations.

Figure 3 illustrates typical results from application of the anisotropic interpolation as applied to Lake Bridgeport. In Figure 3A, deeper channels and steep slopes indicated by surveyed cross-sections are not continuously represented in areas between survey cross-sections. This is an artifact of the TIN generation routine rather than an accurate representation of the physical bathymetric surface. Inclusion of interpolation points in creation of the volumetric TIN model, represented in Figure 3B, directs Delaunay triangulation to better represent the reservoir bathymetry between survey cross-sections. The bathymetry shown in Figure 3C was used in computing reservoir elevation-capacity (Appendix I, M) and elevation-area (Appendix J, N) tables.

**Figure 3.** Anisotropic spatial interpolation as applied to Lake Bridgeport sounding data; A) bathymetric contours without interpolated points, B) sounding points (*black*) and interpolated points (*red*), C) bathymetric contours with interpolated points.

To properly compare results from the 2000 TWDB survey of Lake Bridgeport, the TWDB applied anisotropic spatial interpolation to the survey data collected in 2000. The 2000 survey boundary was digitized from DOQQs photographed on February 2, 1995, while the daily average water surface elevation measured 836.04 feet NGVD29 (Texas Water Development Board, 2000). While linear interpolation was used to estimate the topography in areas without data, flat triangles led to anomalous area and volume calculations at the assigned boundary elevation of 836.00 feet. Therefore, areas between 831.50 feet and 836.00 feet were linearly interpolated between the computed values, and volumes above 831.50 feet were calculated based on the corrected areas (Texas Water Development Board, 2016). Areas above elevation 836.00

feet NGVD29 were linearly extrapolated up to elevation 836.44 feet NGVD29, equivalent to 836.00 feet NAVD88. Capacities were calculated from the extrapolated areas using the formula:

$$\text{Capacity}_1 = \text{Capacity}_0 + \left( \frac{\text{Area}_0 + \text{Area}_1}{2} \right) \times (\text{Elevation}_1 - \text{Elevation}_0)$$

Where:

$\text{Area}_0$  = area corresponding to  $\text{Elevation}_0$

$\text{Area}_1$  = area corresponding to  $\text{Elevation}_1$

$\text{Capacity}_0$  = capacity corresponding to  $\text{Elevation}_0$

$\text{Capacity}_1$  = capacity corresponding to  $\text{Elevation}_1$

The 2000 re-calculated elevation-capacity table and elevation-area table are presented in Appendices A and B, respectively. The re-calculated capacity curve is presented in Appendix C, and the re-calculated area curve is presented in Appendix D.

Although anisotropic spatial interpolation and linear interpolation were originally applied to the 2010 TWDB survey, in 2022, the 2010 TWDB survey of Lake Bridgeport was updated to account for flat triangles. Between the computed area at elevation 829.00 feet and the area of the model boundary at 836.00 feet, areas were linearly interpolated, and volumes above 829.00 feet were calculated based on the corrected areas. To properly compare results from the 2010 TWDB survey of Lake Bridgeport, areas above elevation 836.00 feet NGVD29 were linearly extrapolated up to elevation 836.44 feet NGVD29, equivalent to 836.00 feet NAVD88.

Capacities were calculated from the extrapolated areas using the same formula as above. The 2010 elevation-capacity table and elevation-area table are presented in Appendices E and F, respectively. The capacity curve is presented in Appendix G, and the area curve is presented in Appendix H.

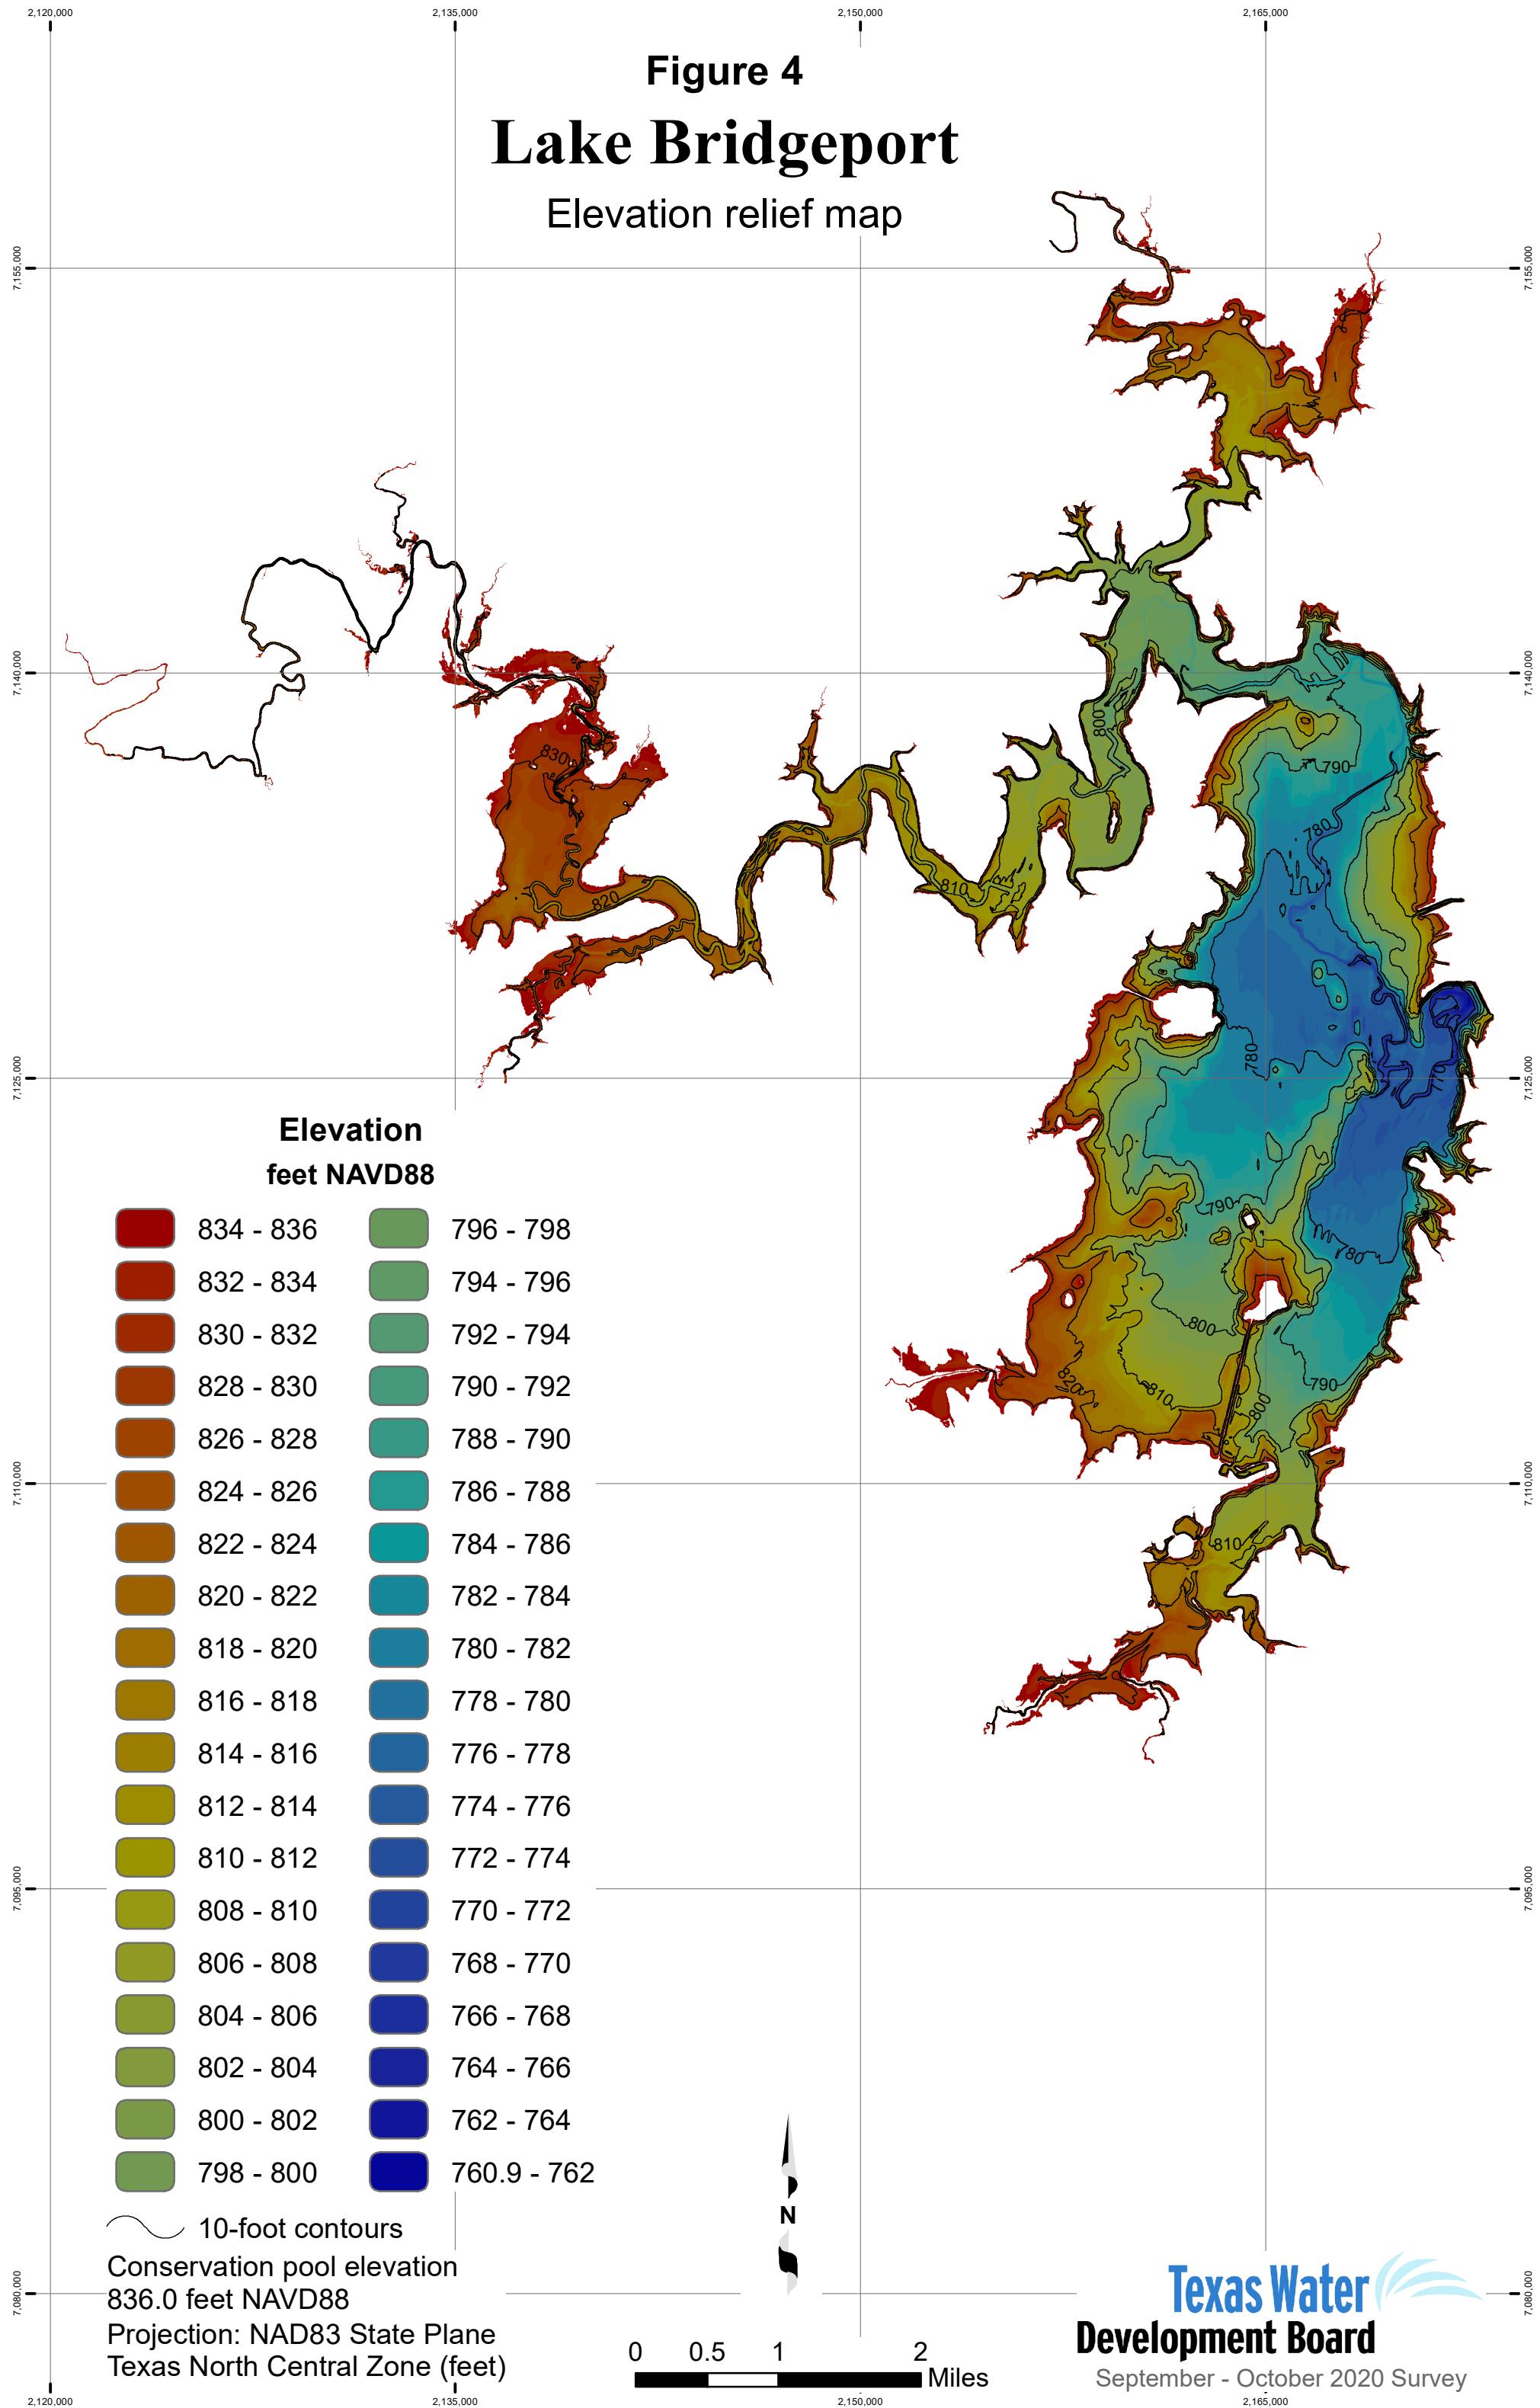

### **Area, volume, and contour calculation**

Volumes and areas were computed for the entire reservoir at 0.1-foot intervals, from 760.7 to 836.2 feet for the bathymetric TIN model, from 760.7 to 874.0 feet for the bathymetric and topographic TIN model, and from 753.0 to 836.2 feet for the pre-impoundment TIN. While linear interpolation was used to estimate the topography in areas without data, flat triangles led to anomalous area and volume calculations at the boundary elevations of 836.2 feet. Therefore, between the computed area at elevation 834.5 feet and the area of the model boundary at 836.2 feet, areas were linearly interpolated, and volumes above 834.5 feet were calculated based on the corrected areas. The bathymetric elevation-capacity table and bathymetric elevation-area table, based on the 2020 survey and analysis, are presented in Appendices I and J, respectively. The bathymetric capacity curve is presented in Appendix K, and the bathymetric area curve is

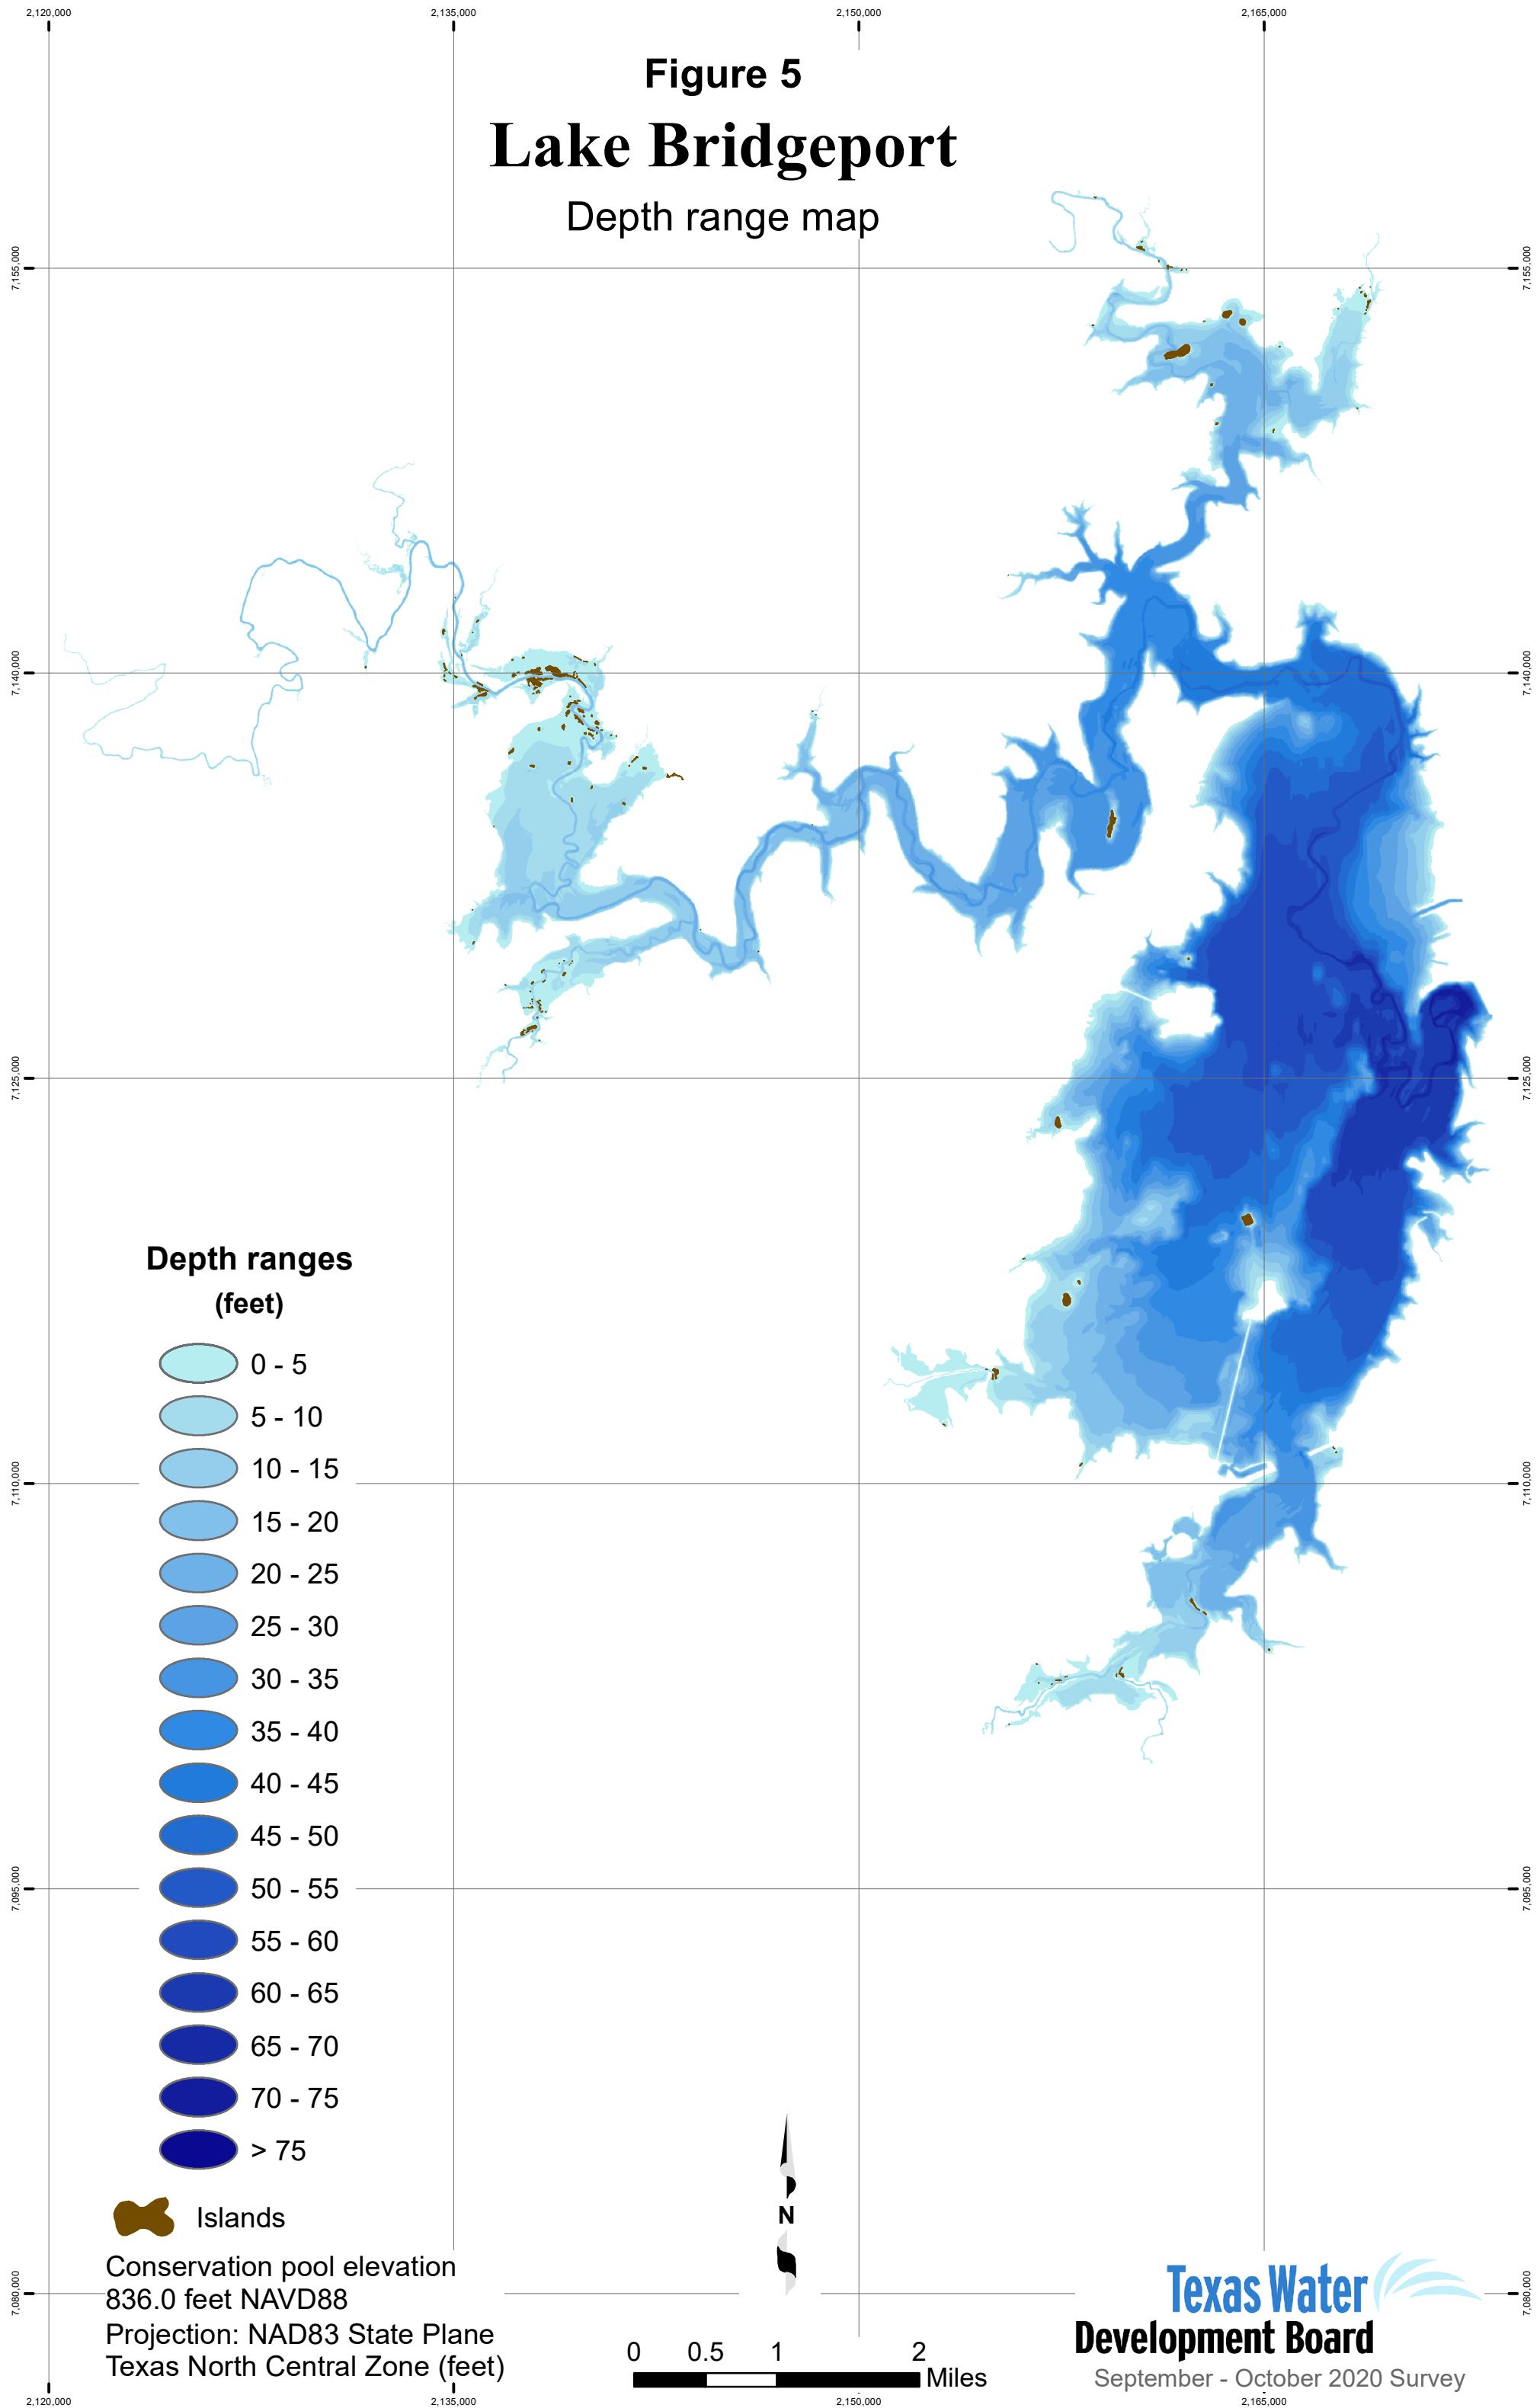

presented in Appendix L. The topographic elevation-capacity table and topographic elevation-area table developed from the 2020 survey and analysis are presented in Appendices M and N, respectively. The topographic capacity curve is presented in Appendix O, and the topographic area curve is presented in Appendix P. The pre-impoundment elevation-capacity table and pre-impoundment elevation-area table, based on the 2020 survey and analysis, are presented in Appendices Q and R, respectively. The pre-impoundment capacity curve is presented in Appendix S, and the pre-impoundment area curve is presented in Appendix T.

The bathymetric volumetric TIN model was converted to a raster representation using a cell size of 2 feet by 2 feet. The raster data then were used to produce three figures: (1) an elevation relief map representing the topography of the reservoir bottom (Figure 4); (2) a depth range map showing depth ranges for Lake Bridgeport (Figure 5); and (3) a 5-foot contour map (Figure 6).

## **Analysis of sediment data from Lake Bridgeport**

Sedimentation in Lake Bridgeport was determined by analyzing the acoustic signal returns of all three depth sounder frequencies using customized software called Hydropick. While the 208 kHz signal is used to determine the current bathymetric surface, the 208 kHz, 50 kHz, and 12 kHz are analyzed to determine the reservoir bathymetric surface at the time of initial impoundment, *i.e.*, pre-impoundment surface. Sediment core samples collected in the reservoir are correlated with the acoustic signals in each frequency to assist in identifying the pre-impoundment surface. The difference between the current surface bathymetry and the pre-impoundment surface bathymetry yields a sediment thickness value at each sounding location.

Sediment cores were analyzed at TWDB headquarters in Austin. Each core was split longitudinally and analyzed to identify the location of the pre-impoundment surface. The pre-impoundment surface was identified within the sediment core using the following methods: (1) a visual examination of the sediment core for terrestrial materials, such as leaf litter, tree bark, twigs, intact roots, *etc.*, concentrations of which tend to occur on or just below the pre-impoundment surface; (2) recording changes in texture from well sorted, relatively fine-grained sediment to poorly sorted mixtures of coarse and fine-grained materials; and, (3) identifying variations in the physical properties of the sediment, particularly sediment water content and penetration resistance with depth (Van Metre and others, 2004). Total sediment core length, post impoundment sediment thickness, and pre-impoundment thickness were recorded. Physical characteristics of the sediment core, such as Munsell soil color, texture, relative water content, and presence of organic materials are presented in Table 2.

**Table 2. Sediment core sample analysis data.**

Sediment core sample	Easting <sup>a</sup> (feet)	Northing <sup>a</sup> (feet)	Total core sample / post-impoundment sediment length (inches)	Sediment core description <sup>b</sup>		Munsell soil color

a. Coordinates are based on NAD83 State Plane Texas North Central System (feet).

b. Sediment core samples are measured in inches with zero representing the current bottom surface.

A photograph of sediment core BRP-4 (for location, refer to Figure 2) is shown in Figure 7. The base, or deepest part of the sample is denoted by the blue line. The pre-impoundment boundary (yellow line closest to the base) was evident within this sediment core sample at 45.0 inches and identified by the change in color, texture, moisture, porosity, and structure. Identification of the pre-impoundment surface for each sediment core followed a similar procedure.

**Figure 7.** Sediment core BRP-4. Post-impoundment sediment layers occur in the top 45 inches of this sediment core (identified by the yellow box). Pre-impoundment sediment layers were identified and are defined by the blue box.

Figure 8 illustrates the relationships between acoustic signal returns and the depositional layering seen in sediment cores. In this example, sediment core BRP-4 is shown correlated with each frequency: 208 kHz, 50 kHz, and 12 kHz. The current bathymetric surface is determined based on signal returns from the 208 kHz transducer as represented by the top red line in Figure 8. The pre-impoundment surface is identified by comparing boundaries observed in the 208 kHz, 50 kHz, and 12 kHz signals to the location of the pre-impoundment surface of the sediment core sample. Many layers of sediment may be identified during analysis based on changes in observed characteristics such as water content, organic matter content, and sediment particle size, and each layer is classified as either post-impoundment or pre-impoundment. Yellow boxes represent post-impoundment sediments identified in the sediment core. Blue boxes indicate pre-impoundment sediments.

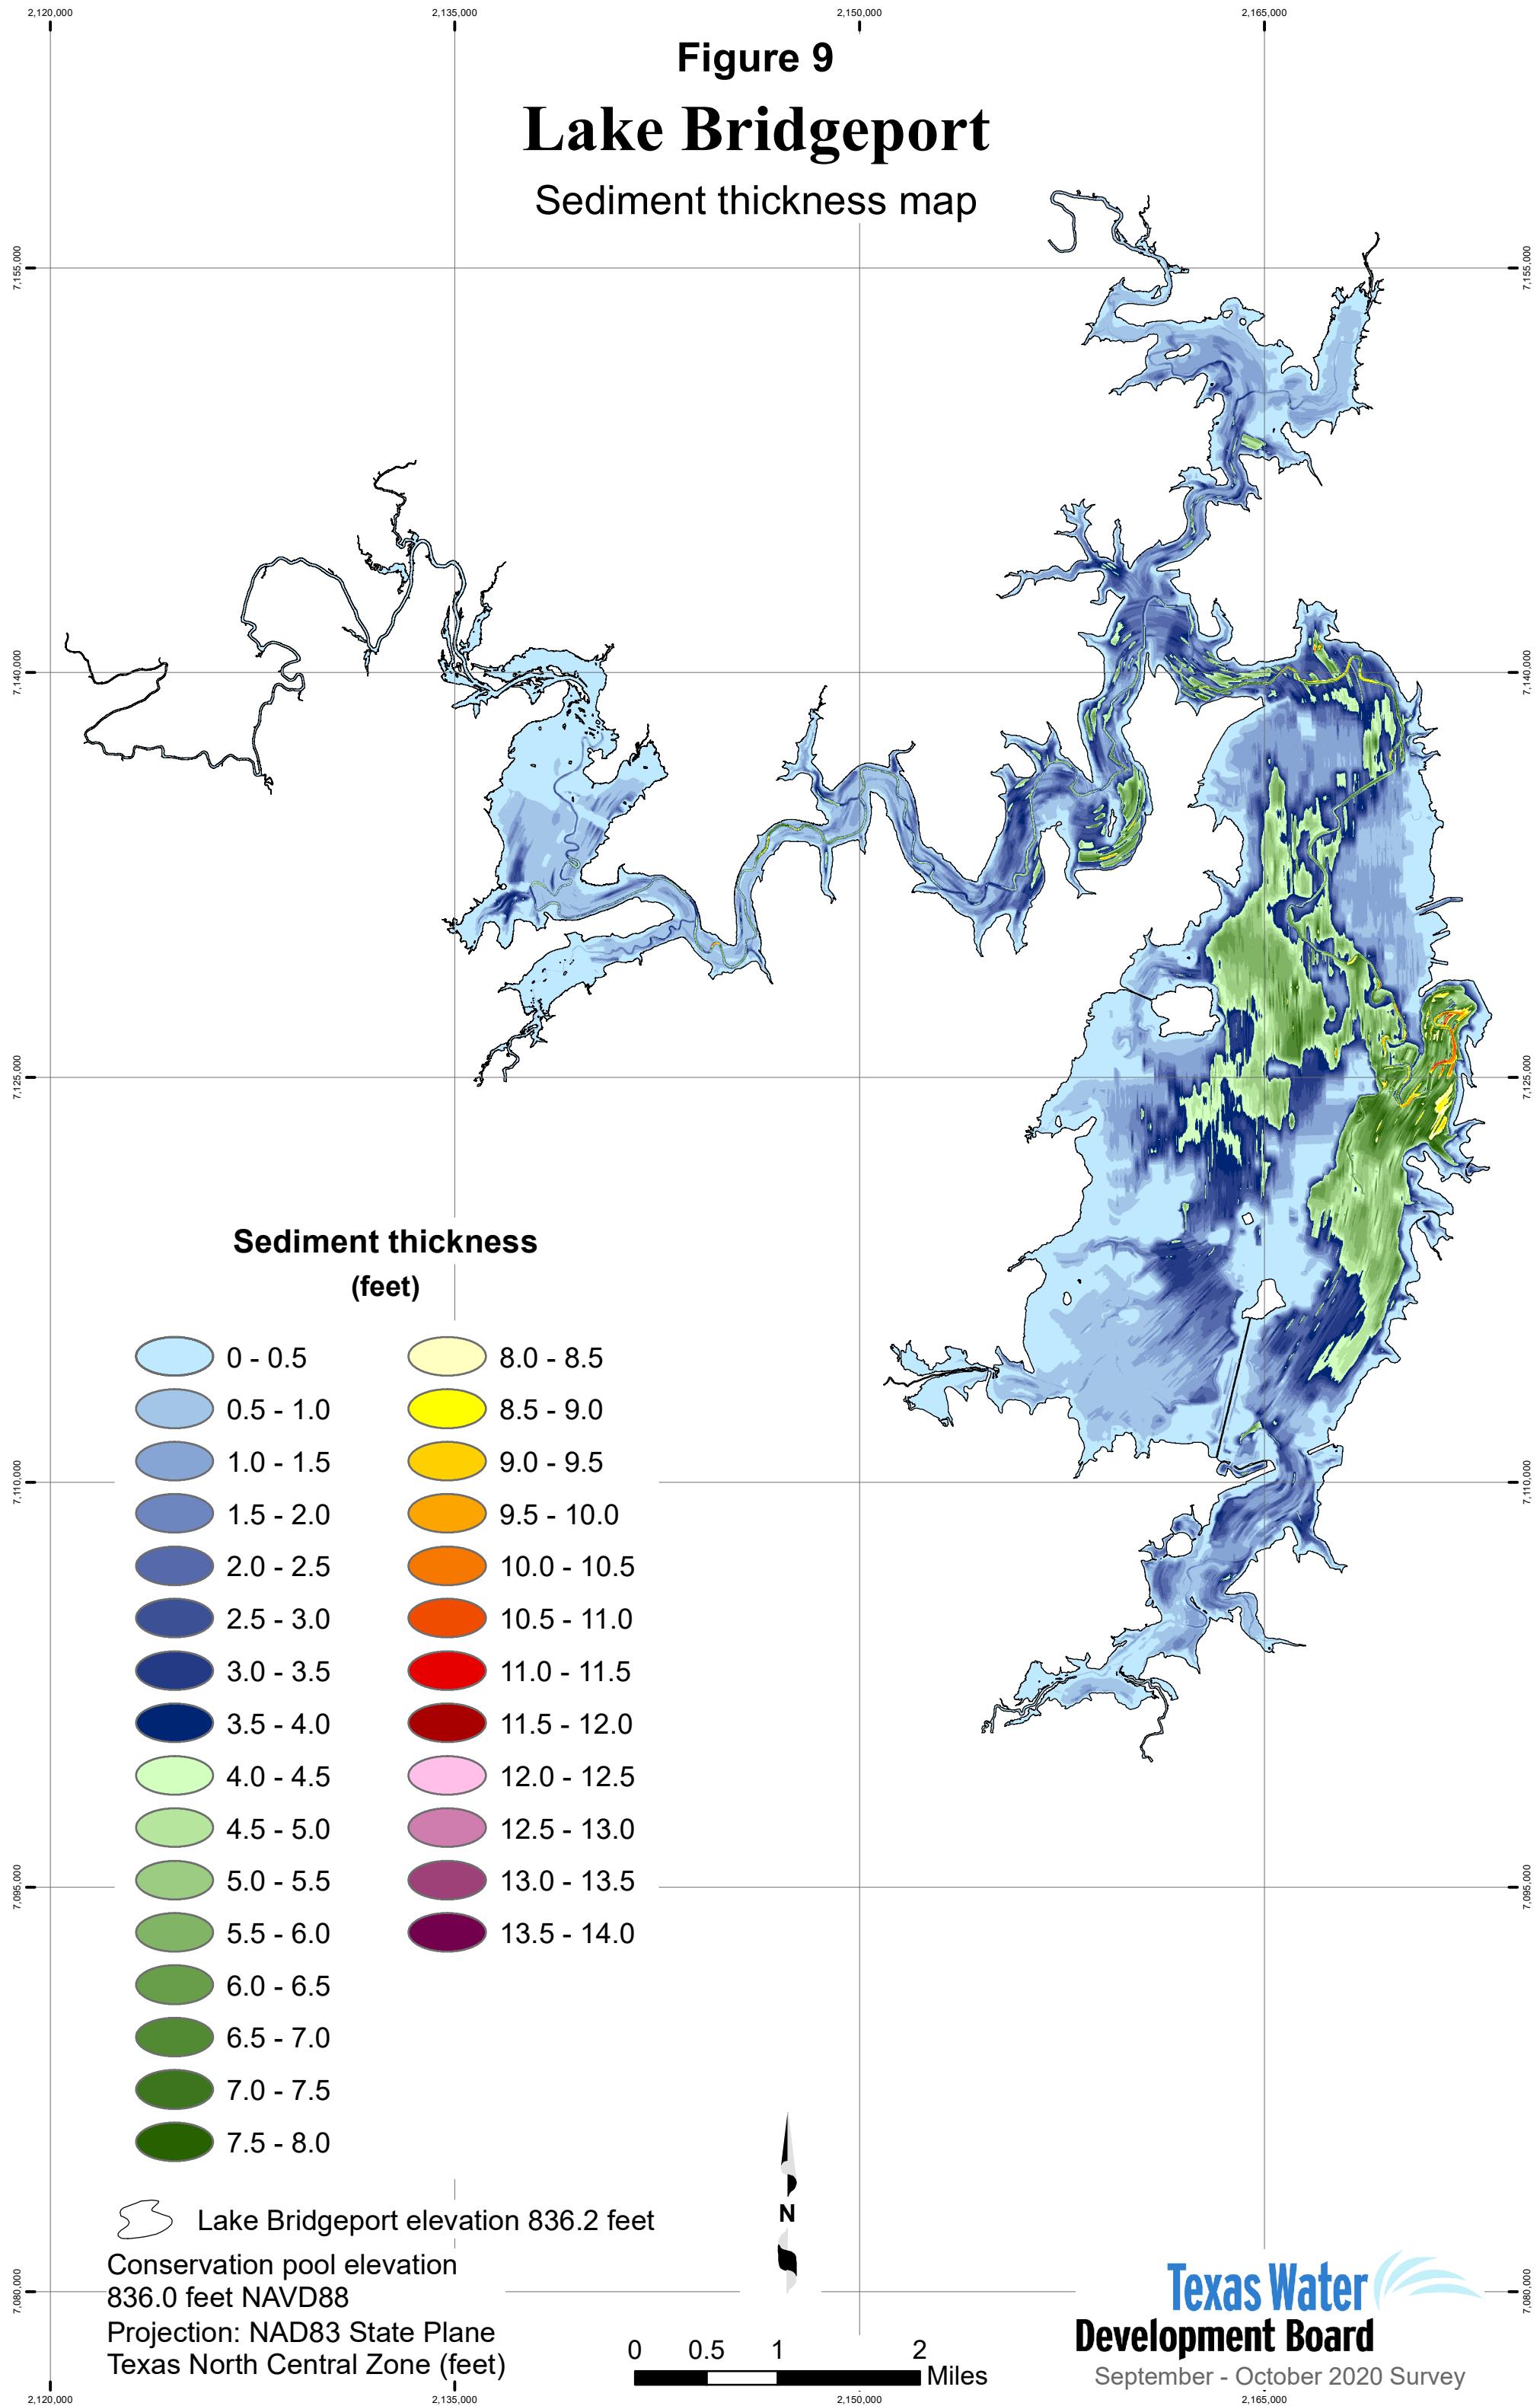

**Figure 8.** Sediment core sample BRP-4 compared with acoustic signal returns. A) 208 kHz frequency, B) 50 kHz frequency, and C) 12 kHz frequency.

The pre-impoundment boundary in sediment core BRP-4 most closely aligned with the different layers picked up by the 208 kHz acoustic returns (Figure 8). The pre-impoundment surface is first identified along cross-sections for which sediment core samples were collected. This information then is used as a guide for identifying the pre-impoundment surface along cross-sections where sediment core samples were not collected.

After the pre-impoundment surface for all cross-sections is identified, a pre-impoundment TIN model and a sediment thickness TIN model are created. Pre-impoundment elevations and sediment thicknesses are interpolated between surveyed cross-sections using HydroTools with the same interpolation definition file used for bathymetric interpolation. For the purposes of TIN model creation, the TWDB assumed the sediment thickness for each LIDAR point and the reservoir boundary was zero feet (defined as the 836.2-foot elevation contour). The sediment thickness TIN model was converted to a raster representation using a cell size of 5 feet by 5 feet and was used to produce a sediment thickness map (Figure 9). Elevation-capacity and elevation-area tables were computed from the pre-impoundment TIN model for the purpose of calculating the total volume of accumulated sediment.

Sediment thickness map

## Survey results

### Volumetric survey

The 2020 TWDB volumetric survey indicates that Lake Bridgeport has a total reservoir capacity of 372,183 acre-feet and encompasses 12,338 acres at conservation pool elevation (836.0 feet NAVD88). Current area and capacity estimates are compared to previous area and capacity estimates in Tables 3 and 4. Because of differences in past and present survey methodologies, direct comparison of volumetric surveys to others to estimate loss of area and capacity can be unreliable.

**Table 3. Surface area and total capacity at conservation pool elevation prior to October 1, 2016.**

<sup>b</sup>. Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (C. Ottman, written commun(s.), 2021).

### Sedimentation survey

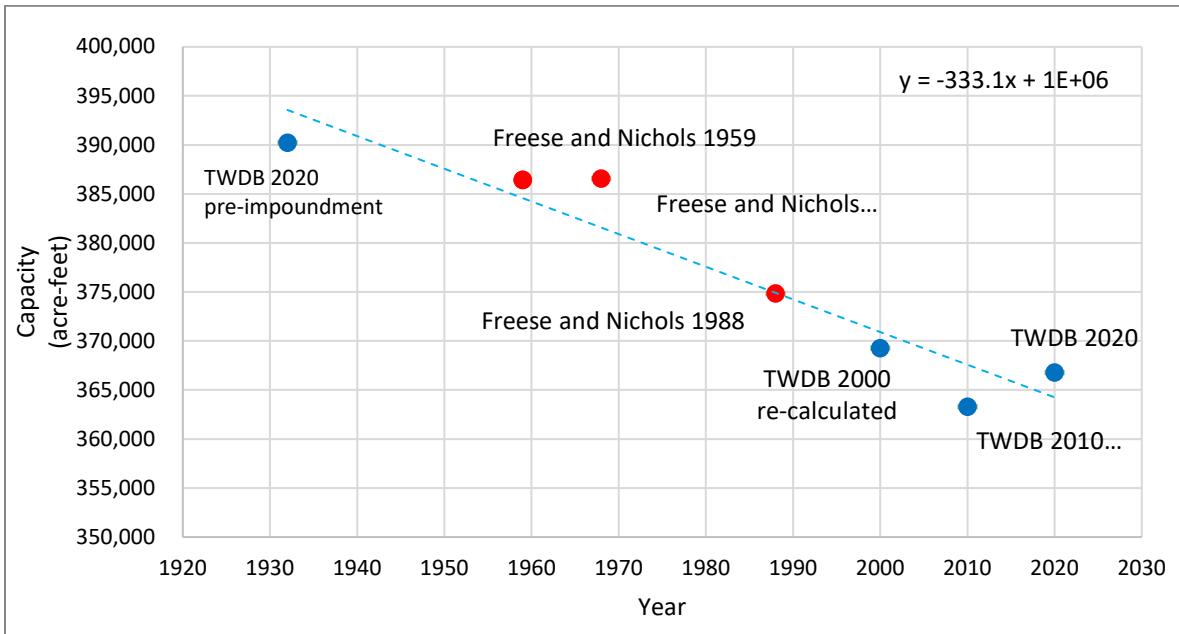

**The 2020 TWDB sedimentation survey measured 23,439 acre-feet of sediment below conservation pool elevation 836.0 feet NAVD88.** The sedimentation survey indicates sediment accumulation is greatest in the river channels and floodplains. The TWDB 2020 pre-impoundment surface is difficult to identify. The original Bridgeport Dam impounded water at a normal operating level of 826.0 feet until the dam was enlarged in 1973. Lake Bridgeport has periodically experienced low water levels leading to the desiccation of any exposed sediment, for instance, between June 2012 and May 2015, the water surface elevation of the reservoir measured as low as 811.73 feet NGVD29. Upon inundation and re-saturation, exposed sediment will not return to its original high level of water content (Dunbar and Allen, 2003). Drying of sediment in exposed areas create hard surfaces that cannot be penetrated with gravity coring techniques, and compressive stresses on the sediments may also increase sediment density, inhibiting the measurement of the original, pre-impoundment surface. Density stratification in the sediment layers can also scatter and attenuate acoustic return signals of the multi-frequency depth sounder (U.S. Army Corps of Engineers, 2013).

Comparisons of capacity estimates of Lake Bridgeport at conservation pool elevation prior to October 1, 2016, and at the original conservation pool elevation 826.0 feet NGVD29, derived using differing methodologies are provided in Tables 5 and 6, respectively, for sedimentation rate calculation. Of sediment measured in the 2020 TWDB survey, 23,437 acre-feet of the total sediment was measured below elevation 835.56 feet NAVD88 (Table 5) and 22,942 acre-feet of the total sediment was measured below elevation 825.56 feet NAVD88 (Table 6). The 2020 TWDB sedimentation survey indicates

Lake Bridgeport has lost capacity at an average of 266 acre-feet per year since impoundment due to sedimentation below conservation pool elevation (836.0 feet NAVD88). Long-term trends indicate Lake Bridgeport loses capacity below elevation 826.0 feet NGVD29/825.56 feet NAVD88 at an average rate of 378 acre-feet per year since impoundment due to sedimentation (Figure 10) and loses capacity below elevation 836.0 feet NGVD29/835.56 feet NAVD88 at an average of 333 acre-feet per year since impoundment due to sedimentation (Figure 11).

**Figure 10.** Plot of current and previous capacity estimates at elevation 826.00 feet NGVD29/825.56 feet NAVD88 (acre-feet). Capacity estimates for each TWDB survey plotted as blue dots and other surveys as red dots. The blue trend line illustrates the total average loss of capacity through 2020.

**Figure 11.** Plot of current and previous capacity estimates at elevation 836.00 feet NGVD29/835.56 feet NAVD88 (acre-feet). Capacity estimates for each TWDB survey plotted as blue dots and other surveys as red dots. The blue trend line illustrates the total average loss of capacity through 2020.

Capacity loss rate (acre-feet/year)	356	293	-41	-627	261
Capacity loss rate (acre-feet/square mile of drainage area of 1,111 square miles /year)	0.32	0.26	-0.04	-0.56	0.23

<sup>c</sup>. Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (C. Ottman, written commun(s), 2021).

<sup>d</sup>. Bridgeport Dam was completed, and deliberate impoundment began in April 1932. The original conservation pool elevation was 826.0 feet NGVD29 (Texas Water Development Board, 1973).

## **Recommendations**

The TWDB recommends a detailed analysis of sediment deposits in the areas where exposure of the lake bottom may have led to identification of a false pre-impoundment using augured-coring techniques, as well as a volumetric and sedimentation survey in 10 years or after a major high flow event to further improve estimates of sediment accumulation rates.

## **TWDB contact information**

For more information about the TWDB Hydrographic Survey Program, visit [www.twdb.texas.gov/surfacewater/surveys](http://www.twdb.texas.gov/surfacewater/surveys). Any questions regarding the TWDB Hydrographic Survey Program or this report may be addressed to: [Hydrosurvey@twdb.texas.gov](mailto:Hydrosurvey@twdb.texas.gov).

Note: Capacities above elevation 831.5 feet calculated from interpolated areas and capacities above 836.0 feet calculated from extrapolated areas

\*Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (equivalent to 836.44 feet NGVD29) (C. Ottman, written commun(s.), 2021).

836	11,952	11,971	11,990	12,009	12,028					

Note: Areas between elevations 831.5 and 836.0 feet linearly interpolated, areas above 836.0 feet linearly extrapolated

\*Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (equivalent to 836.44 feet NGVD29) (C. Ottman, written commun(s.), 2021).

Note: Capacities above elevation 834.5 feet calculated from interpolated areas

\*Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (equivalent to 836.44 feet NGVD29) (C. Ottman, written commun(s), 2021).

836	12,338	12,367	12,395							

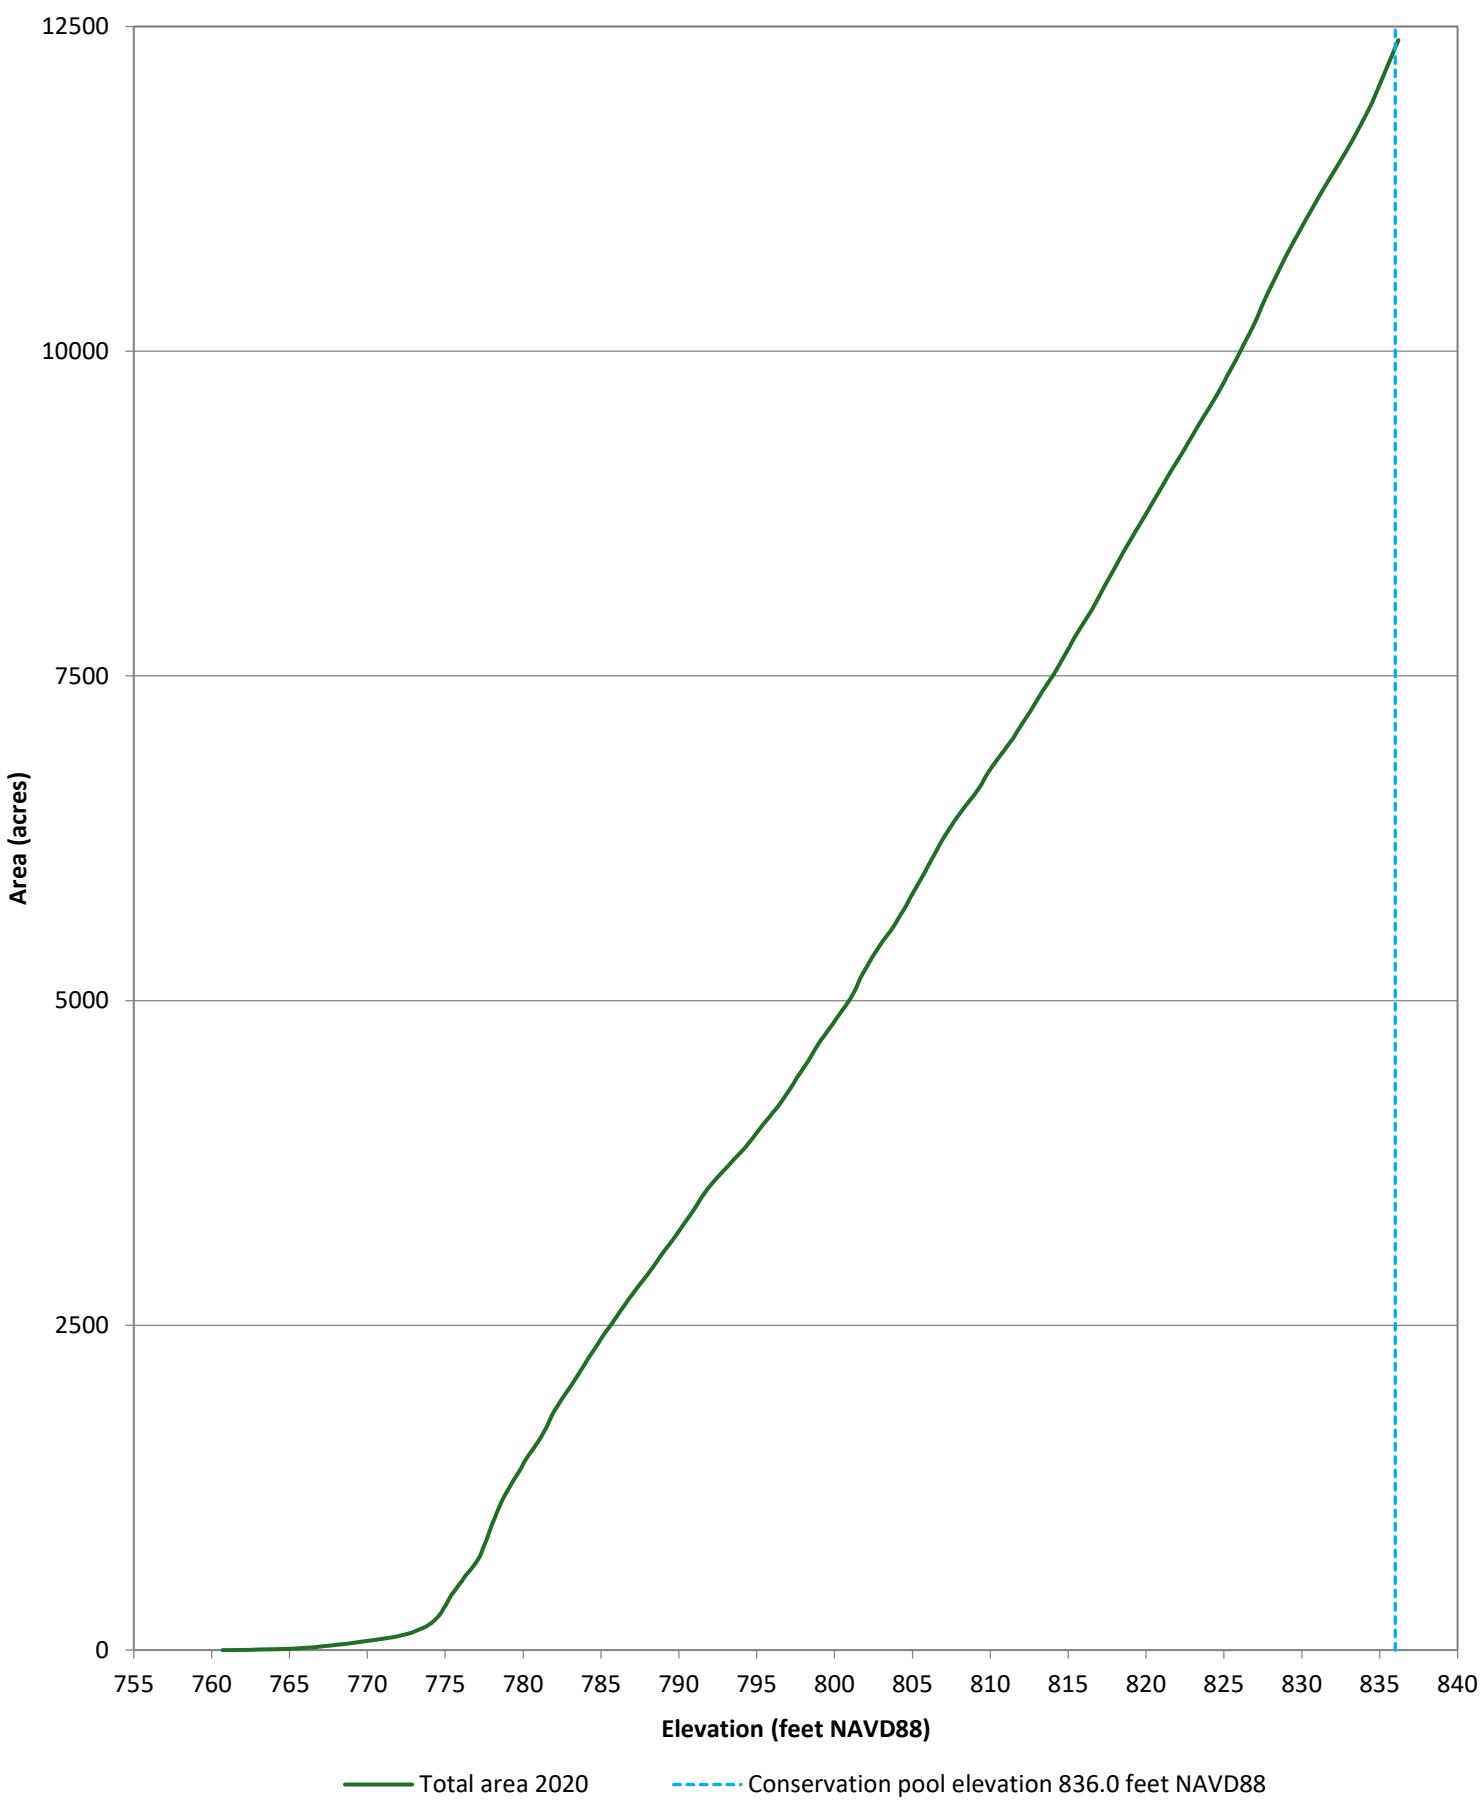

Note: Areas between elevations 834.5 and 836.2 feet linearly interpolated

\*Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (equivalent to 836.44 feet NGVD29) (C. Ottman, written commun(s.), 2021).

874	1,069,223									

Note: Capacities above elevation 834.5 feet calculated from interpolated and computed areas

\*Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (equivalent to 836.44 feet NGVD29) (C. Ottman, written commun(s.), 2021).

874	25,534									

Note: Areas between elevations 834.5 and 836.2 feet linearly interpolated

\*Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (equivalent to 836.44 feet NGVD29) (C. Ottman, written commun(s.), 2021).

Note: Capacities above elevation 834.5 feet calculated from interpolated areas

\*Datum of gage changed from feet National Geodetic Vertical Datum 1929 (NGVD29) to feet North American Vertical Datum 1988 (NAVD88) on October 1, 2016. The new datum is 0.44 feet below previous datum (U.S. Geological Survey, 2021). Conservation pool elevation changed from 836.0 feet NGVD29 to 836.0 feet NAVD88 (equivalent to 836.44 feet NGVD29) (C. Ottman, written commun(s), 2021).
