## **WACO LAKE HYDROGRAPHIC SURVEY REPORT**

### **INTRODUCTION**

Staff of the Hydrographic Survey Unit of the Texas Water Development Board (TWDB) conducted a hydrographic survey on Waco Lake in January, 1995. The purpose of the survey was to determine the capacity of the lake at the normal pool elevation and to establish baseline information for future surveys. From this information, future surveys will be able to determine sediment deposition locations and rates over time. Survey results are presented in the following pages in both graphical and tabular form. All elevations presented in this report will be reported in feet above mean sea level based on the National Geodetic Vertical Datum of 1929 (NGVD '29) unless noted otherwise. The results will be compared to the information from the latest sedimentation survey performed by the U. S. Army Corps of Engineers in 1970. At the normal pool elevation of 455.0 feet, they reported a surface area of 7,237 acres and a capacity of 149,200 acre-feet.

### **HISTORY AND GENERAL INFORMATION OF THE RESERVOIR**

Waco Lake is located on the Bosque River in McLennan County, 4.6 river miles upstream from the confluence of the Bosque and Brazos Rivers. The lake is located within the city limits of Waco and has an estimated drainage area of 1,652 square miles. The lake and dam facility are owned by the United States Government, and maintained and operated by the U. S. Army Corps of Engineers, Fort Worth District (COE). The water rights are allocated to the City of Waco and the Brazos River Authority.

The water right for the original lake (Old Lake Waco-Permit Number 1115) was

issued by the State Board of Water Engineers on August 15, 1929 to the City of Waco authorizing the impoundment of 39,000 acre-feet and the use of not more than 85,000 acre-feet of water annually for municipal water supply in what is now referred to old Lake Waco. In an agreement with the U. S. Government, a new dam was built immediately downstream and a new lake formed that inundated the old lake and dam structure. Permit 1931 was issued on June 6, 1957, amended June 16, 1959, to allow the impoundment of 39,000 acre-feet of water in the new lake, 3,000 ft. downstream of old Lake Waco. The permit was again amended on October 13, 1960, to reduce the annual diversion from 85,000 acre-feet of water to 39,000 acre-feet. Certificate of Adjudication Number 2315 was issued March 8, 1993 to the City of Waco authorizing the City to store 104,100 acre-feet of water in Waco Lake and to use, not more than 58,200 acre-feet of water for municipal purposes per annum and 900 acre-feet per annum for irrigation purposes. On July 16, 1991, Permit Number 5094 was issued by the Texas Water Commission to the Brazos River Authority (BRA). The permit authorized BRA to impound 87,962 acre-feet of water in Waco Lake, and to use, not more than 20,777 acre-feet of water per annum for municipal purposes in McLennan County. The certificate also authorized the use of the impounded waters of Waco Lake for recreational purposes.

Construction of the existing dam commenced in August 1958. Deliberate impoundment of water began February 26, 1965 and the facility was completed June 24 of the same year. The project was designed by the COE and the general contractors were Clement Brothers of Hickory, North Carolina for the earthwork, Elmer Gardner for the spillway, and R. G. LaTourneau, Inc. for the repairs. The estimated project cost was \$49,407,000.

Waco Dam consists of a earthen dam, 24,618 feet long, with a concrete controlled spillway containing fourteen 40 X 35 foot tainter gates. A separate outlet works consisting of one 20 foot diameter conduit is controlled by three 6.8-by-20-foot broome-type tractor sluice gates. The dam has a maximum height of 140 feet above the streambed.

Waco Lake, at the normal pool elevation of 455.0 feet, was originally estimated when built by the COE to have a capacity of 152,500 acre-feet with a surface area of 7,270 acres. In 1970 a resurvey of Waco Lake was performed by the COE in which 24 of the sedimentation range lines were surveyed. The storage volume was calculated at elevation 455.0 to be 149,189 acre-feet with a surface area of 7,237 acres.

## **HYDROGRAPHIC SURVEYING TECHNOLOGY**

The following sections will describe the equipment and methodology used to conduct this hydrographic survey. Some of the theory behind Global Positioning System (GPS) technology and its accuracy are also addressed.

### **GPS Information**

The following is a brief and simple description of Global Positioning System (GPS) technology. GPS is a new technology that uses a network of satellites, maintained in precise orbits around the earth, to determine locations on the surface of the earth. GPS receivers continuously monitor the broadcasts from the satellites to determine the position of the receiver. With only one satellite being monitored, the point in question could be located anywhere on a sphere surrounding the satellite with a radius of the distance measured. The observation of two satellites decreases the possible location to a finite number of points on a circle where the two spheres intersect. With a third satellite observation, the unknown location is reduced to two points where all three spheres intersect. One of these points is obviously in error because its location is in space, and it is ignored. Although three satellite measurements can fairly accurately locate a point on the earth, the minimum number of satellites required to determine a three dimensional position within the required accuracy is four. The fourth measurement compensates for any time discrepancies between the clock on board the satellites and the clock within the GPS receiver.

GPS technology was developed in the 1960s by the United States Air Force and the defense establishment. After program funding in the early 1970s, the initial satellite was launched on February 22, 1978. A four year delay in the launching program occurred after the Challenger space shuttle disaster. In 1989, the launch schedule was resumed. Full operational capability will be reached when the NAVSTAR (NAVigation System with Time And Ranging) satellite constellation is composed of 24 Block II satellites. At the time of the survey, the system had achieved initial operational capability. A full constellation of 24 satellites, in a combination of Block I (prototype) and Block II satellites, was fully functional. The NAVSTAR satellites provide data based on the World Geodetic System (WGS '84) spherical datum. WGS '84 is essentially identical to NAD '83.

The United States Department of Defense (DOD) is currently responsible for implementing and maintaining the satellite constellation. In an attempt to discourage the use of these survey units as a guidance tool by hostile forces, the DOD has implemented means of false signal projection called Selective Availability (S/A). Positions determined by a single receiver when S/A is active result in errors to the actual position of up to 100 meters. These errors can be reduced to centimeters by performing a static survey with two GPS receivers, one of which is set over a point with known coordinates. The errors induced by S/A are time-constant. By monitoring the movements of the satellites over time (one to three hours), the errors can be minimized during post processing of the collected data and the unknown position computed accurately.

Differential GPS (DGPS) can determine positions of moving objects in real-time or "on-the-fly." One GPS receiver was set up over a benchmark with known coordinates established by the hydrographic survey crew. This receiver remained stationary during the survey and monitored the movements of the satellites overhead. Position corrections were determined and transmitted via a radio link once per second to a second GPS receiver located on the moving boat. The boat receiver used these corrections, or differences, in combination with the satellite information it received to determine its

differential location. The large positional errors experienced by a single receiver when S/A is active are greatly reduced by utilizing DGPS. The reference receiver calculates satellite corrections based on its known fixed position, which results in positional accuracies within three meters for the moving receiver. DGPS was used to determine horizontal position only. Vertical information was supplied by the depth sounder.

## **Equipment**

The equipment used in the performance of the hydrographic survey consisted of a 23-foot aluminum tri-hull SeaArk craft with cabin, equipped with twin 90-Horsepower Johnson outboard motors. Installed within the enclosed cabin are an Innerspace Helmsman Display (for navigation), an Innerspace Technology Model 449 Depth Sounder and Model 443 Velocity Profiler, a Trimble Navigation, Inc. 4000SE GPS receiver, a Motorola Radius radio with an Advanced Electronic Applications, Inc. packet modem, and an on-board computer. The computer was supported by a dot matrix printer and a B-size plotter. Power was provided by a water-cooled generator through an in-line uninterruptible power supply. Reference to brand names does not imply endorsement by the TWDB.

The shore station included a second Trimble 4000SE GPS receiver, Motorola Radius radio and Advanced Electronic Applications, Inc. packet modem, and an omni-directional antenna mounted on a modular aluminum tower to a total height of 40 feet. The combination of this equipment provided a data link with a reported range of 25 miles over level to rolling terrain that does not require that line-of-sight be maintained with the survey vessel in most conditions, thereby reducing the time required to conduct the survey.

As the boat traveled across the lake surface, the depth sounder gathered approximately ten readings of the lake bottom each second. The depth readings were averaged over the one-second interval and stored with the positional data to an on-board

computer. After the survey, the average depths were corrected to elevation using the daily lake elevation. The set of data points logged during the survey were used to calculate the lake volume. Accurate estimates of the lake volume can be quickly determined using these methods to produce an affordable survey. The level of accuracy is equivalent to or better than previous methods used to determine lake volumes, some of which are discussed below.

## **Previous Survey Procedures**

Originally, reservoir surveys were conducted with a rope stretched across the reservoir along pre-determined range lines. A small boat would manually pole the depth at selected intervals along the rope. Over time, aircraft cable replaced the rope and electronic depth sounders replaced the pole. The boat was hooked to the cable, and depths were again recorded at selected intervals. This method, used mainly by the Soil Conservation Service, worked well for small reservoirs.

Larger bodies of water required more involved means to accomplish the survey, mainly due to increased size. Cables could not be stretched across the body of water, so surveying instruments were utilized to determine the path of the boat. Monumentation was set for the end points of each line so the same lines could be used on subsequent surveys. Prior to a survey, each end point had to be located (and sometimes reestablished) in the field and vegetation cleared so that line of sight could be maintained. One surveyor monitored the path of the boat and issued commands via radio to insure that it remained on line while a second surveyor determined depth measurement locations by turning angles. Since it took a major effort to determine each of the points along the line, the depth readings were spaced quite a distance apart. Another major cost was the land surveying required prior to the reservoir survey to locate the range line monuments and clear vegetation.

Electronic positioning systems were the next improvement. If triangulation could determine the boat location by electronic means, then the boat could take continuous

depth soundings. A set of microwave transmitters positioned around the lake at known coordinates would allow the boat to receive data and calculate its position. Line of site was required, and the configuration of the transmitters had to be such that the boat remained within the angles of 30 and 150 degrees in respect to the shore stations. The maximum range of most of these systems was about 20 miles. Each shore station had to be accurately located by survey, and the location monumented for future use. Any errors in the land surveying resulted in significant errors that were difficult to detect. Large reservoirs required multiple shore stations and a crew to move the shore stations to the next location as the survey progressed. Land surveying was still a major cost.

Another method used mainly prior to construction utilized aerial photography to generate elevation contours which could then be used to calculate the volume of the reservoir. Fairly accurate results could be obtained, although the vertical accuracy of the aerial topography was generally one-half of the contour interval or  $\pm$  five feet for a ten-foot contour interval. This method could be quite costly and was only applicable in areas that were not inundated.

## **PRE-SURVEY PROCEDURES**

The reservoir's surface area was determined prior to the survey by digitizing with AutoCad software the lake's normal pool boundary from three USGS quad sheets. The names of the quad sheets are as follows: Speegleville, TX, 1957 (Photo-revised 1970 and 1975); Waco West, TX, 1957 (Photo-revised 1970 and 1975); and South Bosque, TX, 1965 (Revised 1993).

The survey layout was designed by placing survey track lines at 500 foot intervals across the lake. The survey design for this lake required approximately 145 survey lines to be placed along the length of the lake. Survey setup files were created using Innerspace Technology Inc. software for each group of track lines that represented a specific section of the lake. The setup files were copied onto diskettes for use during the

field survey.

## **SURVEY CONTROL SETUP**

The first task of the Hydrographic Survey field staff after arriving at Waco Lake was to establish a horizontal reference control point. Figure 3 shows the location of the control point established. This location was chosen due to the close proximity to the reservoir and the security of the area.

Prior to the field survey, TWDB staff had researched locations of known first-order benchmarks and requested Brazos River Authority employees to physically locate the associated monuments. Of the monuments found, the one chosen to provide horizontal control for the survey was a United States Geological Survey first-order monument named PAYNE 1919 located approximately 1.5 miles west of China Springs, Texas. The coordinates for the monument are published as Latitude 31° 39' 53.33051"N and Longitude 97° 19' 37.21359"W.

On January 5, 1995, TWDB staff performed a static survey to determine the WGS'84 coordinates of the lake survey control point, an existing surveyor's cap labeled G900-1Q set flush to the ground in concrete and located on the crest of the dam between the outlet works and the spillway. The static survey was performed from the PAYNE 1919 monument to the control point using two Trimble 4000SE GPS receivers. The GPS receivers were setup on tripods over each point and satellite data were gathered for approximately one hour, with up to six satellites visible at the same time to the receivers.

Once data collection ended, the data were retrieved and processed from both receivers, using Trimble Trimvec software, to determine the coordinates for the control point. The WGS' 84 coordinates for G900-1Q were determined to be North latitude 31° 35' 03.57873" and West longitude 97° 12' 08.23326".

Using the newly determined coordinates, a shore station was setup at G900-1Q to provided DGPS control during the survey. The coordinates from the static survey were entered into the GPS receiver located over the control point to fix its location. Data received during the survey could then be corrected and broadcast to the GPS receiver on the moving boat during the survey.

## **SURVEY PROCEDURES**

The following procedures were followed during the hydrographic survey of Waco Lake performed by the TWDB. Information regarding equipment calibration and operation, the field survey, and data processing is presented.

### **Equipment Calibration and Operation**

During the survey, the GPS receivers were operated in the following DGPS modes. The reference station receiver was set to a horizontal mask of  $0^\circ$ , to acquire information on the rising satellites. A horizontal mask of  $10^\circ$  was used on the roving receiver for the purpose of calculating better horizontal positions. A PDOP (Position Dilution of Precision) limit of 7 was set for both receivers. The DGPS positions are known to be within acceptable limits of horizontal accuracy when the PDOP is seven (7) or less. An internal alarm sounds if the PDOP rises above seven to advise the field crew that the horizontal position has degraded to an unacceptable level.

Prior to the survey, TWDB staff verified the horizontal accuracy of the DGPS used during the Waco Lake survey to be within the specified accuracy of three meters by the following procedure. The shore station was set up over a known United States Geological Service (USGS) first order monument and placed in differential mode. The

second receiver, directly connected to the boat with its interface computer, was placed over another known USGS first order monument and data was collected for 60 minutes in the same manner as during a survey. Based on the differentially-corrected coordinates obtained and the published coordinates for both monuments, the resulting positions fell within a three-meter radius of the actual known monument position.

At the beginning of each surveying day, the depth sounder was calibrated with the Innerspace Velocity Profiler. The Velocity Profiler calculates an average speed of sound through the water column of interest for a designated draft value of the boat (draft is the vertical distance that the boat penetrates the water surface). The draft of the boat was previously determined to average 1.2 ft. The velocity profiler probe is placed in the water to moisten and acclimate the probe. The probe is then raised to the water surface where the depth is zeroed. The probe is lowered on a cable to just below the maximum depth set for the water column, and then raised to the surface. The unit displays an average speed of sound for a given water depth and draft, which is entered into the depth sounder. The depth value on the depth sounder was then checked manually with a measuring tape to ensure that the depth sounder was properly calibrated and operating correctly. During the survey of Waco Lake, the speed of sound in the water column varied daily between 4,762 and 4,777 feet per second. Based on the measured speed of sound for various depths, and the average speed of sound calculated for the entire water column, the depth sounder is accurate to within  $\pm 0.2$  feet, plus an estimated error of  $\pm 0.3$  feet due to the plane of the boat for a total accuracy of  $\pm 0.5$  feet for any instantaneous reading. These errors tend to be minimized over the entire survey, since some are plus readings and some are minus readings. Further information on these calculations is presented in Appendix A.

## **Field Survey**

Data was collected on Waco Lake during the period of January 9-13, 1995. Approximately 71,622 data points were collected over the 128 miles traveled along the

pre-planned survey lines and the random data-collection lines. These points were stored digitally on the boat's computer in 160 data files. Data were not collected in areas of shallow water (depths less than 3.0 ft.) or with significant obstructions unless these areas represented a large amount of water. Random data points were collected, when determined necessary by the field crew, by manually poling the depth and entering the depth value into the data file. As each point was entered, the DGPS horizontal position was stored automatically with each return keystroke on the computer. The boat was moving slowly during this period so positions stored were within the stated accuracy of  $\pm$  3 meters to the point poled. Figure 2 shows the actual location of the data collection points.

Analog charts were printed for each survey line as the data were collected. The gate mark, which is a known distance above the actual depth, was also printed on the chart. Each chart was labeled with the date and data file ID for future reference. The depth sounder was set to record bad depth readings as 0.

The collected data were stored in individual data files for each pre-plotted range line or random data collection events. These files were downloaded to diskettes at the end of each day for further processing.

## **Data Processing**

All collected data were down-loaded from diskettes onto the TWDB's computer network. The diskettes were then stored in a secured, safe location for future reference as needed. A Fortran program stripped the data collection files of non-essential data and created a Temporary data file. This data file consists of latitude, longitude and depth readings for each data point. The depth readings consist of instantaneous, average and auxiliary readings. The data files were edited manually by comparing the analog charts to the gate mark. Where the gate mark indicated that the recorded depth was other than the bottom, the depths were modified to reflect the recorded bottom.

The Temporary files were then saved as Output files after editing was completed. The Output files were run through another Fortran program to delete all zero depth readings and to replace the average reading with the spot reading when the average reading was zero and the spot reading was greater than zero. The resulting file was saved as the final data file. Each of the individual data files were then combined into a single data-collection file that represented the date of data collection. The depths were then transformed to elevations with a simple Unix command based on the water surface elevation of each day. The elevations were rounded to the nearest tenth of a foot since the depth sounder records in tenths. The water surface ranged from 455.29 to 455.56 feet during the survey. Each of the daily files were then combined into a single edited data file to be used to develop a model of the lake's bottom surface.

The resulting DOS data file was imported into the UNIX operating system used to run Environmental Systems Research Institutes's (ESRI) Arc/Info GIS software. The latitude and longitude coordinates of each point were then converted to decimal degrees by a UNIX awk command. The awk command manipulates the data file format into a MASS points format for use by the GIS software. The graphic boundary file used for guidance along the pre-plotted survey lines was then transformed from NAD '27 datum to NAD '83, using Environmental Systems Research Institutes's (ESRI) Arc/Info project command with the NADCOM parameters. The area of the lake boundary was checked to verify that the area was the same in both datums. Once this was accomplished successfully, the boundary and the edited data file were in the same datum.

The two files are edited using the Arc/Edit module. The MASS points are converted into a point coverage and plotted on top of the boundary file. If data points were collected outside the boundary file, the boundary was modified to include the data points. The boundary near the edges of the lake in areas of significant sedimentation was down-sized to reflect the observations of the field crew. The resulting boundary shape was considered to be the acreage at the normal pool elevation of the lake. This was calculated as 7,194 acres for Waco Lake. The Board does not represent the boundary, as depicted in this report, to be a detailed actual boundary. Instead, it is a

graphical approximation of the actual boundary used solely to compute the volume and area of the lake. The boundary does not represent the true land versus water boundary of the lake. An aerial topographic map of the upper four feet of the lake or an aerial photo taken when the lake is at the normal pool elevation would more closely define the present boundary. However, the minimal increase in accuracy does not appear to offset the cost of those services at this time.

The edited MASS points and modified boundary file were used to create a Digital Terrain Model (DTM) of the reservoir's bottom surface using Arc/Info's TIN module. The module builds an irregular triangulated network from the data points and the boundary file. This software uses a method known as Delauney's criteria for triangulation. A triangle is formed between three non-uniformly spaced points, including all points along the boundary. If there is another point within the triangle, additional triangles are created until all points lie on the vertex of a triangle. All of the data points are preserved for use in determining the solution of the model by using this method. The generated network of three-dimensional triangular planes represents the actual bottom surface. Once the triangulated irregular network (TIN) is formed, the software then calculates elevations along the triangle surface plane by solving the equations for elevation along each leg of the triangle. Areas that were too shallow for data collection or obstructed by vegetation were estimated by the Arc/Info's TIN product using this method of interpolation.

There were some areas where values could not be calculated by interpolation because of a lack of information along the boundary of the reservoir. "Flat triangles" were drawn at these locations. Arc/Info does not use flat triangle areas in the volume or contouring features of the model. These areas were determined to be insignificant on Waco Lake. Therefore no additional points were required for interpolation and contouring of the entire lake surface. The TIN product calculated the surface area and volume of the entire reservoir at one-tenth of a foot intervals from the three-dimensional triangular plane surface representation. The computed reservoir volume table is presented in Appendix B and the area table in Appendix C. An elevation-area-volume graph is presented in Appendix D.

Other presentations developed from the model include a shaded relief map and a shaded depth range map. To develop the shaded relief map, the three-dimensional triangular surface was modified by a GRIDSHADE command. Colors were assigned to different elevation values of the grid. Using the command COLORRAMP, a set of colors that varied from navy to yellow was created. The lower elevation was assigned the color of navy, and the lake normal pool elevation was assigned the color of yellow. Different color shades were assigned to the different depths in between. Figure 4 presents the resulting depth shaded representation of the lake. Figure 5 presents a similar version of the same map, using bands of color for selected depth intervals. The color increases in intensity from the shallow contour bands to the deep water bands.

The DTM was then smoothed and linear smoothing algorithms were applied to the smoothed model to produce smoother contours. The resulting contour map of the bottom surface at ten-foot intervals is presented in Figure 6.

## RESULTS

Staff of the TWDB collected hydrographic data on Waco Lake during the period January 9-13, 1995. During the survey period, the lake maintained a water surface elevation above the conservation pool elevation, facilitating boat access to the majority of the lake. The survey crew observed during the survey that the bathymetry of the lake seemed to correspond to the relief of the shoreline. Gentle lake bottom slopes were noted on the North Bosque River and the western banks of the Middle and South Bosque Rivers, similar to the slopes of the surrounding land. The eastern banks of the Middle and South Bosque Rivers were marked by more severe dropoffs along the cliffs or rapidly rising shoreline areas. The survey vessel was able to collect data along the North Bosque River, upstream to the Eichelberger Crossing, but encountered areas of standing and fallen trees, stumps, and silt deposits from the area of the Bosque Bend Clubhouse upstream to the Highway 105 bridge. From the 105 bridge upstream to the Eichelberger

Crossing, the lake represented more of a river segment. On the Middle and South Bosque Rivers, large silt deposits as well as stumps and fallen timber were encountered in the areas upstream of Midway Park. The survey crew also made note during the survey, that large trees and other debris were still located on the upstream slope of the dam marking the high water elevation reached during the December, 1990 flood.

Results from the 1995 survey indicate Waco Lake now encompasses around 7,194 surface acres and contains a volume of 144,830 acre-feet at the normal pool elevation of 455.0 feet. The lowest elevation encountered during the field survey was 378.66 feet, or 76.34 feet of depth and was found near the dam.

The storage volume calculated by the 1995 survey is approximately 2.9 percent less than the 1970 previous record information for the lake. The lowest gated outlet invert elevation is at elevation 400.0 feet. The dead storage volume in the lake at this elevation corresponds to 284 acre-ft. Therefore, the conservation storage capacity for the lake is calculated to be 144,546 acre-feet. This corresponds to a 2.75 percent decrease in the conservation storage capacity of the lake.

## SUMMARY

Waco Dam and Lake were authorized by the Flood Control Act approved 3 September, 1954 and construction commenced in August 1958. From October 1, 1964 to February 26, 1965, the lake was operated as a detention basin only. On February 26, 1965, old Lake Waco was breached and deliberate impoundment began. Initial storage calculations estimated the volume of the lake at the conservation pool elevation of 455.0 to be 152,500 acre-feet with surface area of 7,270 acres. In 1970, a sedimentation survey of Waco Lake was performed by US Army Corps of Engineers (COE). The volume of the lake was revised to 149,189 acre-feet at the conservation pool elevation with a surface area of 7,237 acres. The COE estimated that Waco Lake had accumulated 3,311 acre-feet of sediment between 1965 and 1970. The average annual

sediment accumulation rate for the 5.85 year period was estimated at 566 acre-feet per year, or 0.34 acre-feet deposited annually per square mile of drainage area in the conservation pool area. This rate was lower than the calculated rate of 0.79 acre-feet per square mile and could have been influenced by excavation along the sedimentation range lines, during the period between the original cross-sections and the resurvey, that were used in the computations.

In January 1995, a hydrographic survey of Waco Lake was performed by the Texas Water Development Board's Hydrographic Survey Program. The 1995 survey used technological advances such as differential global positioning system and geographical information system technology to build a model of the reservoir's bathymetry. These advances allowed a survey to be performed quickly and to collect significantly more data of the bathymetry of Waco Lake than the previous surveys. Results from the survey indicate that the lake's capacity at the normal pool elevation of 455.0 feet was 144,830 acre-feet. The estimated reduction in storage capacity, if compared to the 1970 survey information, was 4,370 acre-feet, or 2.9 percent. This equates to an estimated loss of 174.8 acre-feet per year during the 25 years between the TWDB's survey and the last survey performed by the COE, or an annual deposition rate in the conservation pool area of 0.105 acre-ft per square mile of drainage area.

It is difficult to compare the surveys performed by the TWDB and the COE because the methods and procedures used were very different. However, the TWDB considers the 1995 survey to be a significant improvement over previous survey procedures and recommend that the same methodology be used to re-surveyed Waco Lake in five to ten years or after major flood events. A second survey will remove any noticeable error due to improved calculation techniques and will isolate current sedimentation rates and the storage losses occurring in Waco Lake.

## CALCULATION OF DEPTH SOUNDER ACCURACY

This methodology was extracted from the Innerspace Technology, Inc. Operation Manual for the Model 443 Velocity Profiler.

For the following examples,  $t = (D - d)/V$

where:  $t_D$  = travel time of the sound pulse, in seconds (at depth = D)  
D = depth, in feet  
d = draft = 1.2 feet  
V = speed of sound, in feet per second

To calculate the error of a measurement based on differences in the actual versus average speed of sound, the same equation is used, in this format:

$$D = [t(V)]+d$$

For the water column from 2 to 30 feet:  $V = 4832$  fps

$$\begin{aligned} t_{30} &= (30-1.2)/4832 \\ &= 0.00596 \text{ sec.} \end{aligned}$$

For the water column from 2 to 45 feet:  $V = 4808$  fps

$$\begin{aligned} t_{45} &= (45-1.2)/4808 \\ &= 0.00911 \text{ sec.} \end{aligned}$$

For a measurement at 20 feet (within the 2 to 30 foot column with  $V = 4832$  fps):

$$\begin{aligned} D_{20} &= [(20-1.2)/4832](4808)+1.2 \\ &= 19.9' \quad (-0.1') \end{aligned}$$

For a measurement at 30 feet (within the 2 to 30 foot column with  $V = 4832$  fps):

$$\begin{aligned} D_{30} &= [(30-1.2)/4832](4808)+1.2 \\ &= 29.9' \quad (-0.1') \end{aligned}$$

For a measurement at 50 feet (within the 2 to 60 foot column with  $V = 4799$  fps):

$$\begin{aligned} D_{50} &= [(50-1.2)/4799](4808)+1.2 \\ &= 50.1' \quad (+0.1') \end{aligned}$$

For the water column from 2 to 60 feet:  $V = 4799 \text{ fps}$       Assumed  $V_{80} = 4785 \text{ fps}$

$$\begin{aligned}t_{60} &= (60-1.2)/4799 \\&= 0.01225 \text{ sec.}\end{aligned}$$

For a measurement at 10 feet (within the 2 to 30 foot column with  $V = 4832 \text{ fps}$ ):

$$\begin{aligned}D_{10} &= [(10-1.2)/4832)(4799)]+1.2 \\&= 9.9' \quad (-0.1')\end{aligned}$$

For a measurement at 30 feet (within the 2 to 30 foot column with  $V = 4832 \text{ fps}$ ):

$$\begin{aligned}D_{30} &= [(30-1.2)/4832)(4799)]+1.2 \\&= 29.8' \quad (-0.2')\end{aligned}$$

For a measurement at 45 feet (within the 2 to 45 foot column with  $V = 4808 \text{ fps}$ ):

$$\begin{aligned}D_{45} &= [(45-1.2)/4808)(4799)]+1.2 \\&= 44.9' \quad (-0.1')\end{aligned}$$

For a measurement at 80 feet (outside the 2 to 60 foot column, assumed  $V = 4785 \text{ fps}$ ):

$$\begin{aligned}D_{80} &= [(80-1.2)/4785)(4799)]+1.2 \\&= 80.2' \quad (+0.2')\end{aligned}$$
